The conclusions in the Report titled LA GRANDE ALLIANCE FEASIBILITY STUDY – PHASE I PRELIMINARY GEOTECHNICAL INVESTIGATION – POTENTIAL BDH RAILWAY are Stantec's professional opinion, as of the time of the Report, and concerning the scope described in the Report. The opinions in the document are based on conditions and information existing at the time the scope of work was conducted and do not take into account any subsequent changes. The Report relates solely to the specific project for which Stantec was retained and the stated purpose for which the Report was prepared. The Report is not to be used or relied on for any variation or extension of the project, or for any other project or purpose, and any unauthorized use or reliance is at the recipient's own risk.

Stantec has assumed all information received from Cree Development Corporation (the "Client") and third parties in the preparation of the Report to be correct. While Stantec has exercised a customary level of judgment or due diligence in the use of such information, Stantec assumes no responsibility for the consequences of any error or omission contained therein.

This Report is intended solely for use by the Client in accordance with Stantec's contract with the Client. While the Report may be provided to applicable authorities having jurisdiction and others for whom the Client is responsible, Stantec does not warrant the services to any third party. The report may not be relied upon by any other party without the express written consent of Stantec, which may be withheld at Stantec's discretion.

1.0 Introduction

1.1 General

La Grande Alliance refers to the Memorandum of Understanding (MOU) on the Cree-Québec Sustainable Infrastructure Program in Eeyou Istchee Baie-James, signed between the Cree Nation Government (CNG) and the Government of Québec on February 17, 2020. The purpose of the MOU is to provide a framework for Cree local and regional entities to work closely with relevant Québec government ministries to connect, develop and protect the territory of the Eeyou Istchee Baie-James region of northern Québec in an inclusive and participatory manner. The main objective of La Grande Alliance is to build a promising program for the strategic, predictable, and sustainable development of the territory over a 30-year time horizon.

Infrastructure development is a major component of *La Grande Alliance*. The program aims at improving and building major transportation infrastructure on the territory, including the implementation of a railway alongside the Billy-Diamond Highway to Whapmagoostui, where the construction of a deep-water port is being considered. The current program is divided into three phases. Phase I being carried out by Vision Eeyou Istchee Consortium, focusing on the feasibility design of the following infrastructures:

- Upgrade of the existing access roads between the Billy-Diamond Highway (BDH) and the Cree communities of Waskaganish, Eastmain and Wemindji;
- Upgrade of the existing access road between the Route du Nord and the community of Nemaska;
- New railway along the Billy-Diamond Highway (BDH) between the town of Matagami and KM 257 of the same highway (Rupert River Bridge);
- Recommissioning of the railway line from Grevet (Lebel-sur-Quévillon) to Chapais (approximately 225 km);
- Construction of transfer areas along the Billy-Diamond Highway and Grevet-Chapais line corridors, specifically the area at KM 257;
- Upgrade of the Route du Nord, and;
- Construction of a secondary access road to the Cree Nation of Mistissini.

The location of the infrastructures listed above is shown on Figure 1.

Limitations associated with this report and its contents are provided in the Statement of General Conditions included in Appendix A.

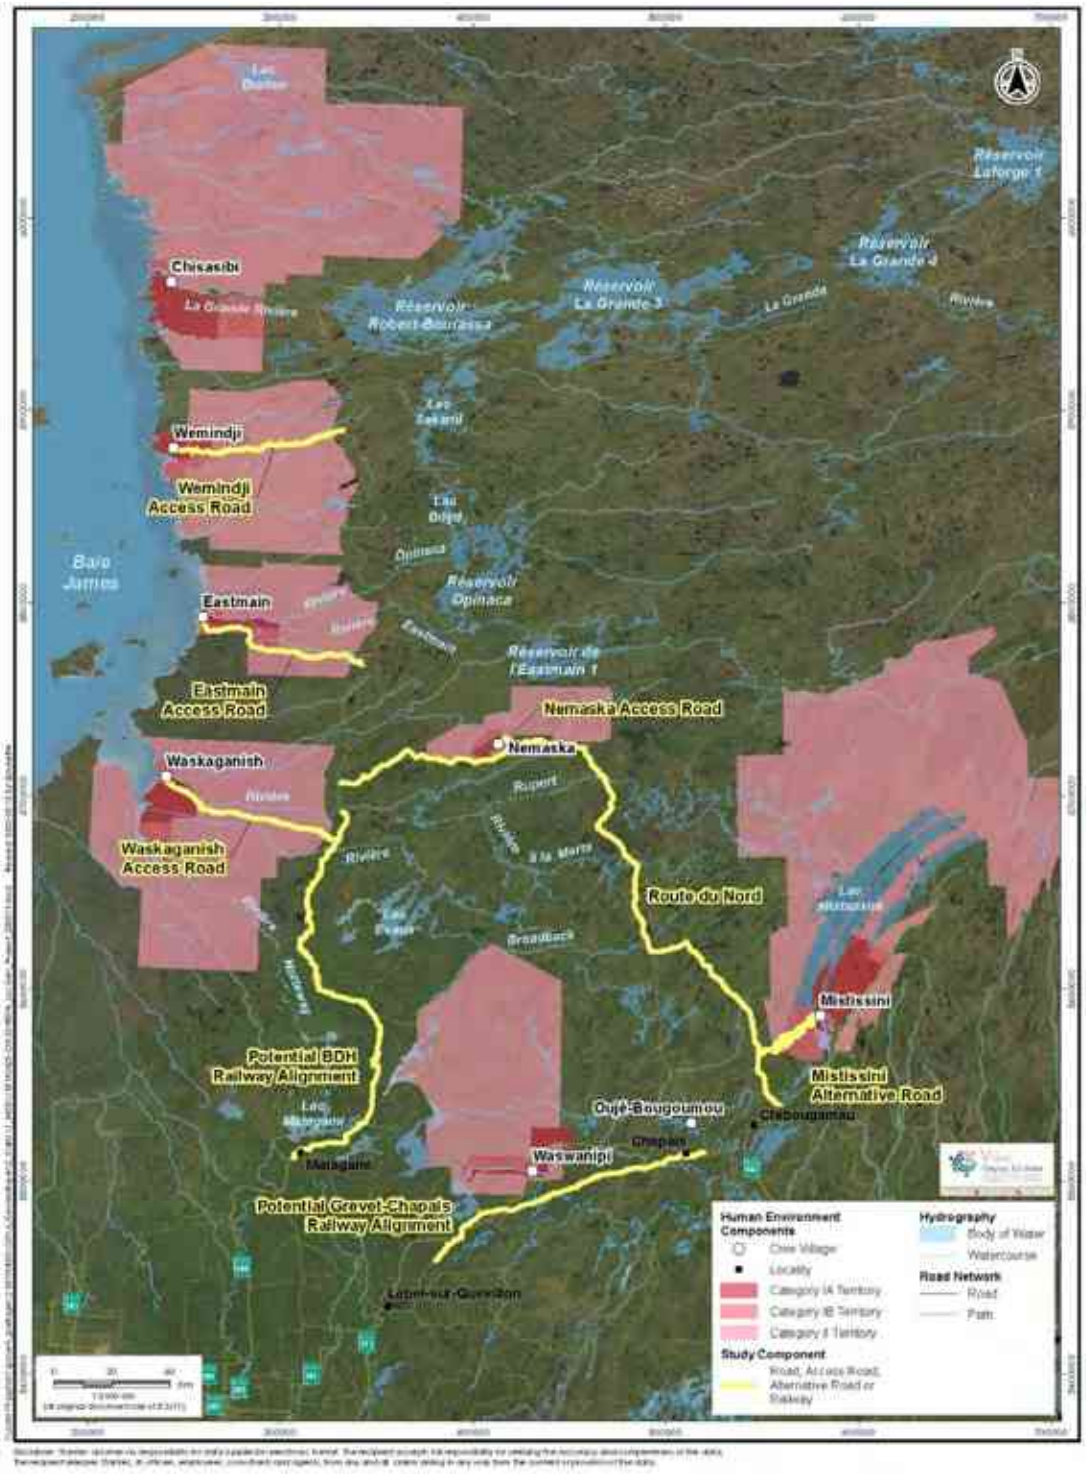

Figure 1 La Grande Alliance – Phase I Feasibility Study Area Overview

1.2 Scope of Work and Objective

As part of the Feasibility Study, the scope of work included carrying out a Preliminary Geotechnical Investigation for some of the transportation infrastructure corridors listed in Section 1.1 of this report.

The current report focuses on the potential Billy-Diamond Highway (BDH) Railway alignment located between the town of Matagami and the bridge of the Rupert River on the BDH, (the “Site”).

The preliminary geotechnical investigation was carried out to determine the site characteristics with regards to the nature and properties of soils and bedrock in place, and to identify areas with organic soil deposits (peats). The information gathered during this investigation was used to estimate the baseline in-situ conditions at the Site that feeds the Feasibility Study for the preliminary design of the potential BDH railway.

1.3 Site and Project Description

The project consists of the design, development, and construction of a new railway that will extend from the town of Matagami at south (KP 0) to the Rupert River at north (KP 253). It should be noted that the term « KM » will be used in this report to refer to the kilometer mark of the BDH while the term « KP » will be used to refer to the kilometer point of the future railway. A key plan showing the location of the Site is presented in Figure 2 below and in Appendix B.

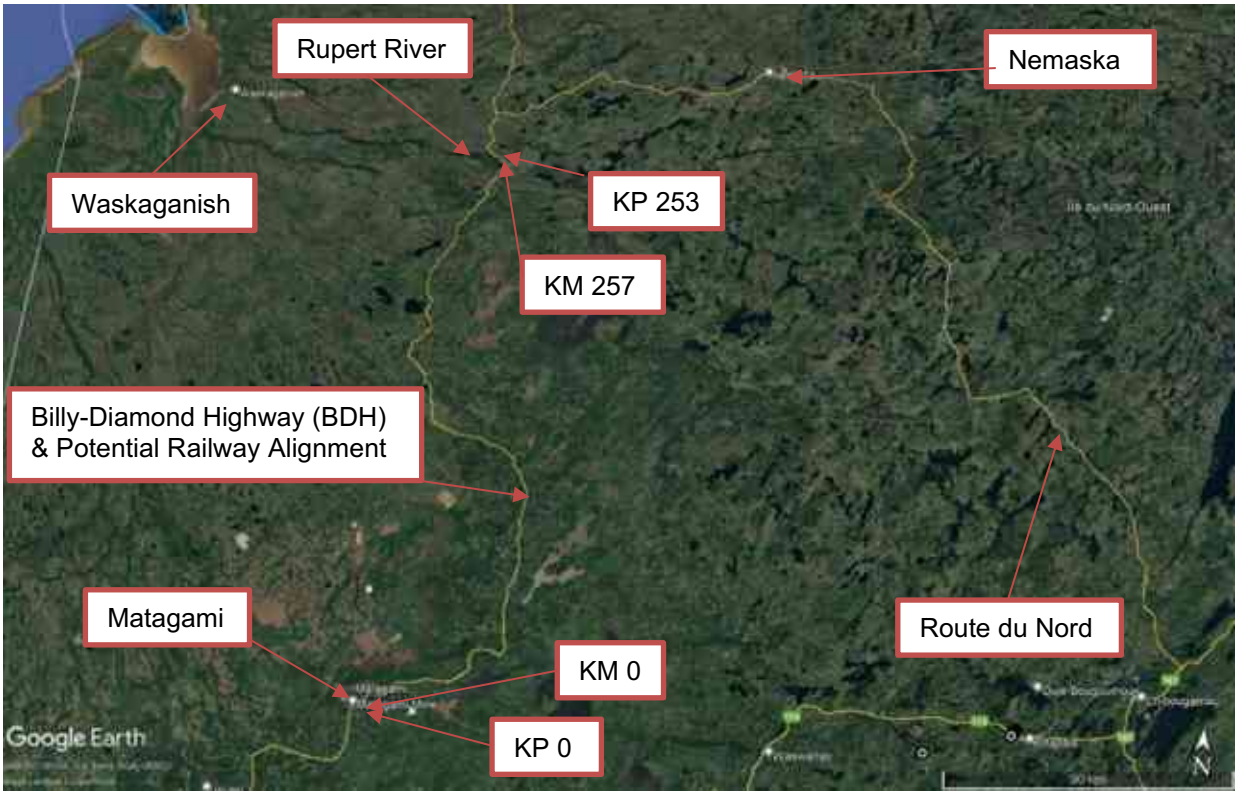

Figure 2 Potential BDH Railway Location (Google Earth)

The potential BDH railway alignment closely follows the actual alignment of the Billy-Diamond Highway and deviates from it at a maximum distance of 4 km in some localized sectors. The railway will be built on mineral and organic soils, in forested and undeveloped areas. A significant portion of the railway will be built on peat; these areas will require special geotechnical attention during the next design phases.

Bridges and culverts will be constructed along the alignment to cross rivers and streams, as well as the Billy-Diamond Highway at some location. The geodetic elevations range from el. ≈290 m at Matagami to el. ≈190 m at the Rupert River Bridge. Several high embankments are also anticipated throughout the proposed alignment.

2.0 Method of Investigation

2.1 Environmental permitting

Before undertaking any geotechnical work on the targeted territory, Vision Eeyou Ischee has ensured to obtain the necessary authorizations and permits for the execution of the work:

- Land use (MERN);
- Tree cutting (MFFP), and;
- Declaration of compliance (MELCC).

All activities conducted on the territory (land occupancy, wood cutting, preparation of accesses and drilling) were carried out in compliance with the current laws and regulations. Also, following the completion of the fieldwork, effort was made at each of the investigated sites to minimize the impact of the work.

2.2 Utility Locates

A request was filed by Stantec to Info-excavation to identify underground public utilities present in the vicinity of the work site. Where present, all identified utilities were marked on the ground prior to the execution of the field work.

2.3 Health and Safety

The Stantec employees who participated in this project familiarized themselves with all the relevant Stantec Safe Work Practices (SWPs) prior to beginning of any fieldwork. In addition, Stantec's pre-job Health and Safety Checklist, that identifies any health and safety risks, was filled out and signed by all the participants in the fieldwork, including the subcontractors. The goal of this document is to identify any potential dangers in order to prevent accidents and injuries from occurring. No health and safety incidents occurred while Stantec was present at the Site.

2.4 Geotechnical Field Investigation

A site investigation specific to the peat areas was carried out as part of this program. The objective was to obtain a preliminary characterization of the organic deposits along the proposed rail alignment. The investigation was carried out using a manual auger and included measuring the thickness of the organic soils, and sampling both the organic and the underlying soils. Organic soils were classified using the Von Post scale. Undrained shear strength testing using a portable field vane was carried out where possible. Results of peat investigation are presented in Appendix E of this report.

In addition, 41 boreholes, identified BH22-01 to BH22-43, were drilled as part of the investigation; two of the initially planned boreholes (BH22-19 and BH22-23) could not drilled. These boreholes were drilled to obtain general information on the geotechnical properties of the soils at future bridge and culvert

locations, as well as at the high embankment sites. They were advanced using a CME drill rig mounted on tracks operated by *Forage Boislard* Inc. under the constant supervision of an experienced Stantec technician. The borehole reports are presented in Appendix C.

At each borehole, the soils were sampled at regular intervals using a 610 mm long and 51 mm external diameter split spoon sampler (*B* size sampler) or a 63 mm external diameter split spoon sampler (*N* size sampler). With the *B* size sampler, the Standard Penetration Tests (SPTs) was recorded as defined in ASTM D-1586. The soils collected from split-spoon samplers were examined and described, and the soil recovery measured and recorded.

The SPT test consists of counting the numbers of blows required to drive a *B* size sampler 12 in. (305 mm) into a soil by means of a 140 lb (63.5 kg) mass falling a height of 30 in. (762 mm). The blow count is referred to as the N-value of the soil, which is a description of its state of compactness.

Shelby tube samplers, or thin-walled hollow steel tubes, were pushed into the ground to extract relatively undisturbed cohesive soil samples during the drilling activities in accordance with ASTM D-1587.

Field vane shear tests were carried out in 12 boreholes to determine the undrained shear strength of intact and remoulded clays at various depths in accordance with ASTM D-2573.

Dynamic cone penetration test (DCPT) was carried out in boreholes B22-06, BH22-09, BH22-15, BH22-24, BH22-30, BH22-31, BH22-34, BH22-35, BH22-36, and BH22-41 after sampling in accordance with BNQ 2501-145. The dynamic cone penetration is a continuous test which uses a drop-weight to drive a cone and rod into the ground. The number of blows for each 12 in. (305 mm) of penetration is recorded until reaching refusal on very dense soils, cobbles, boulders, or bedrock. A continuous resistance versus depth profile is obtained from the dynamic cone penetration test which can provide a visual relationship of soil type or density variations.

The bedrock coring was carried out in boreholes BH22-01, BH22-03, BH22-04, BH22-05, BH22-07, BH22-08, BH22-10, BH22-18, BH22-26, BH22-27, BH22-32, BH22-33, BH22-38, BH22-39, BH22-40, and BH22-43. Conventional rock coring was used to advance the boreholes into bedrock and obtain continuous samples of rock in accordance with ASTM D-2113. A 75.7 mm diameter hole was drilled using a diamond-impregnated, annular, rotary drill bit with an inner diameter of 47.7 mm (*NQ* size sampler). A double inner tube system to recover the rock core samples was used. Throughout the drilling process, water was used as a circulation fluid to both lubricate and cool the drill bit. Geological and engineering descriptions, and rock quality designation (RQD) were recorded on the borehole log for each core run. Rock cores from each borehole were placed in core boxes and transferred to our Laval laboratory.

The field work was conducted under the supervision of engineering staff from Stantec who maintained detailed logs of the subsurface and drilling conditions encountered and obtained representative samples of the various strata encountered. Soils were classified in accordance with the Unified Soil Classification System (USCS) ASTM D-2487 and D-2488. All soil samples were stored in moisture proof bags and returned to our laboratory in Laval, Quebec, for selected laboratory testing. Rock core samples were inspected and logged by Stantec personnel at the borehole locations prior to being transferred to our

laboratory for detailed geological logging and storage. Handling, transportation and storage of soil and bedrock samples were undertaken with care to minimize disturbance.

Standpipe piezometers were installed in boreholes BH22-06, BH22-09, BH22-14, BH22-15, BH22-24, BH22-27, BH22-28, BH22-29, BH22-30, BH22-33, and BH22-37 to allow for the measurement of groundwater levels. The standpipes consisted of 20 mm diameter rigid pipes with a 1.5 m length of screen installed at the bottom of each well, then backfilled with silica sand up to 0.3 m above the top of the screen. The boreholes were sealed with bentonite hole plug.

2.5 Site Survey

Sounding locations for the peat investigation was provided by the geomorphology specialist, based on available cartographic maps. At this stage of the feasibility study, a limited number of test holes per peat area was proposed. It is thus possible that additional peat areas are still to be identified. Coordinates of each sounding location were determined using a handheld GPS providing a 3 m precision. Test hole locations are presented in a summary table in Appendix E.

The geotechnical borehole locations were selected by the team carrying out the project Feasability Study in order to characterize of the *in-situ* conditions at the bridge and culvert locations, as well as the high embankment locations within the future alignment. The boreholes were positioned on Site using the same GPS type, and when the boreholes were drilled at a different location than initially targeted, the new coordinates were recorded by the field technician.

No geodetic elevations were measured during this investigation. All depths presented in this report refer to the ground surface level at the time of the investigation as « meter below ground surface (mbgs) ».

The geodetic coordinates at each borehole location are presented below and are shown on the borehole location plans in Appendix B and the borehole reports in Appendix C. It should be noted that the kilometer point (KP) indicated in this report were provided by the rail design team, based on the latest version of the alignment available at the time of writing this report.

Table 1 Borehole Location and Description

Borehole	Geodetic Coordinates UTM Zone 18		Kilometer Point (KP)	Description
	East (m)	North (m)		
BH22-01	312 812	5 516 753	9.5	High Embankment (5 m)
BH22-02	317 844	5 518 782	15.5	High Embankment (13 m)
BH22-03	316 142	5 652 368	204.8	High Embankment (4 m)

Borehole	Geodetic Coordinates UTM Zone 18		Kilometer Point (KP)	Description
	East (m)	North (m)		
BH22-43	313 971	5 643 339	194.9	High Embankment (5 m)

2.6 Laboratory Testing

All collected samples returned to our laboratory were subjected to a detailed visual examination and additional classification by a geotechnical engineer. The following geotechnical laboratory tests were performed on selected samples:

Table 2 Geotechnical Laboratory Tests

Laboratory Testing	Standards	Number of Tests
Grain-size distribution by mechanical sieve (coarse soil fraction)	BNQ 2501-025	125
Grain-size distribution by hydrometer test (fine soil fraction)	BNQ 2501-025	87
Atterberg Limits	BNQ 2501-092	37
Water content	BNQ 2501-170	152
Undrained shear strength by fall cone test	BNQ 2501-110	23
One-dimensional consolidation test	ASTM D-2435	11
Unit Weights	--	38
Compressive strength of intact rock core specimen	ASTMD-7012	11

The results of the laboratory tests are discussed in the text of this report and are presented in Appendix D.

The soil samples will be stored for a period of 12 months after issuing of the final report. Samples will then be discarded unless otherwise directed.

3.0 Subsurface Conditions

3.1 Surficial Material Mapping

Surficial material mapping was conducted along a 250 m wide corridor centered on the potential BDH Railway alignment. Surficial material mapping uses training, experience and expert judgement in the identification and delineation of geomorphological landforms visible on the Earth's surface to interpret and classify the landscape. It provides the basis to support the geotechnical study and helps with the decision-making process to be conducted as part of the following phases of the project.

The surficial material mapping was carried out through the interpretation of available satellite imagery (Google Earth, ESRI and Forêt Ouverte World Imagery) and LiDAR data (provided by the client, 2022). The LiDAR data were processed to create bare-earth hillshade images and one-meter interval contour lines. Available background information (e.g., surficial geology mapping, literature relevant to the terrain conditions) were considered while conducting the mapping. The mapping was also updated based on the results obtained from the geotechnical and peat investigation programs.

For this project, relatively homogeneous terrain units were identified and codified using a texture-oriented classification system inspired from the Hydro-Quebec legend, which is largely used in the James Bay region. The classification system used is presented in Table 3 below.

Table 3 Surficial Material Mapping Legend

Surficial Material Classification	
R	> 80 % of bedrock
T	Till
SG	Sand and Gravel
S	Sand
SM	Silty sand or sandy silt
CM	Clayey silt or silty clay
Pt	Peat
B	Boulders*
BE	Existing borrow Source
N	Water body
Ant	Anthropogenic

*No thickness was interpreted for boulder accumulations

Examples of layer overlapping and thickness	
Sm/T	Thin layer of sand (< 2 m thick) over till
S/T	Layer of sand (2 to 6 m thick) over till
S	Sand (> 6 m thick)

Examples of combined symbols	
T+B	Till with boulders at the ground surface
R+Tm/R	Bedrock with a veneer of till (< 2 m thick)
T-SG	Undifferentiated till or sand and gravel

A surficial material map atlas was produced at a scale of 1:15,000 and is presented in Appendix F. Table 4 below presents a statistical summary of the dominant surficial material identified along the potential Billy-Diamond railway alignment.

Table 4 Surficial Material along the Potential BDH Railway Alignment

Dominant surficial material	Distance along the potential BDH Railway Alignment	
	Length (km)	Percent (%)
Clayey silt or silty clay (CM)	75.20	29.8
Peat (Pt)	52.57	20.8
Silty sand or sandy silt (SM)	47.86	19.0
Till (T)	44.50	17.6
Sand (S)	13.36	5.3
Bedrock (R)	8.48	3.4
Sand and gravel (SG)	7.67	3.0
Existing borrow source (BE)	1.73	0.7
Water body (N)	0.88	0.3
Anthropogenic (Ant)	0.25	0.1
Boulders (B)	-	-
Total	**252.50**	**100.0**

3.2 Peat Investigation

The near coastal clayey plains in James-Bay are usually very rich in organic deposits. As presented in the previous section, the proposed rail alignment crosses about 50 km (20% of total length) of peat areas. For this report, peat areas refer to an organic deposit where flora has been accumulating and decomposing over a long period of time in a poorly drained environment. Each peat area presents usually a thin active top layer above a mix of organic material at different stages of decomposition. This material has a poor bearing capacity and produces large settlements when loaded (DLC, 2012).

The initial soil mapping was carried out using available arial photos to identify the peat locations and the expected surface of each peat area within the proposed alignment. This desktop study identified about 120 peat areas. For each area, test holes were then proposed to collect field data for further identification.

Field data collection included recording the peat thickness, measuring its shear strength, and identifying the nature of the soils underlying the peat. In addition, a brief description of the surroundings was captured (vegetation, body of water, proximity forest, human activities, topography, surface boulders, etc.) The results of this investigation are presented in Appendix E.

As stated, the number of test holes was limited for this feasibility study and the results should be considered as preliminary. It is recommended that a complementary detailed investigation of the peat areas be carried out at a later design stage. Of the 120 peat areas, 51 were identified as having more than 500 mm of peat like material. Based on the observed stratigraphy in the soundings, the average thickness of the organic layer varied between 0.3 and 1.5 m. However, the thickness extended to between 1.5 and 3.0 m in some areas. In general, the organics thickness was more important in the northern section of the proposed alignment.

All auger retrieved samples were visually analyzed and classified using the Von Post scale system. It is based of the degree of decomposition of the organic matter, with H1 being completely non-decomposed and H10 completely decomposed. The classification table is presented below (Figure 3):

Degree of Humification (VON POST)	Decomposition	Plant structure	Amorphous material	Colour of released water	Escape of material on squeezing	Nature of residue
H1	None	Easily identified	None	Clear	None	
H2	Insignificant	Easily identified	None	Clear or yellowish	–	
H3	Very slight	Still identifiable	–	Muddy brown	–	Not pasty
H4	Slight	Not easily identifiable	Very slight amount	–	None	Somewhat pasty
H5	Moderate	Recognizable but vague	–	–	Very small amount	–
H6	Moderately strong	Indistinct	–	–	About one third escapes	Fibres and roots more resistant to decomposition remain in hand
H7	Strong	Very faintly recognizable	Lots	Very dark and almost pasty	About one half escapes	
H8	Very strong	Very indistinct	Large quantity	–	About two thirds escape;	
H9	Nearly complete	Almost undiscernable	–	–	–	
H10	Complete	Not discernable	–	–	All the wet peat escapes	

Figure 3 Von Post Classification

For this study, a total of 120 peat areas have been recognized, and the Von Post classification showed a wide variation across the proposed alignment. Each peat area will require a further investigation. In general, the most frequent class varies from H3 (very slight decomposition) to H7 (strong decomposition). In addition, several locations showed no or insignificant decomposition (H1 and H2). The following chart illustrate the class distribution for the identified peat areas:

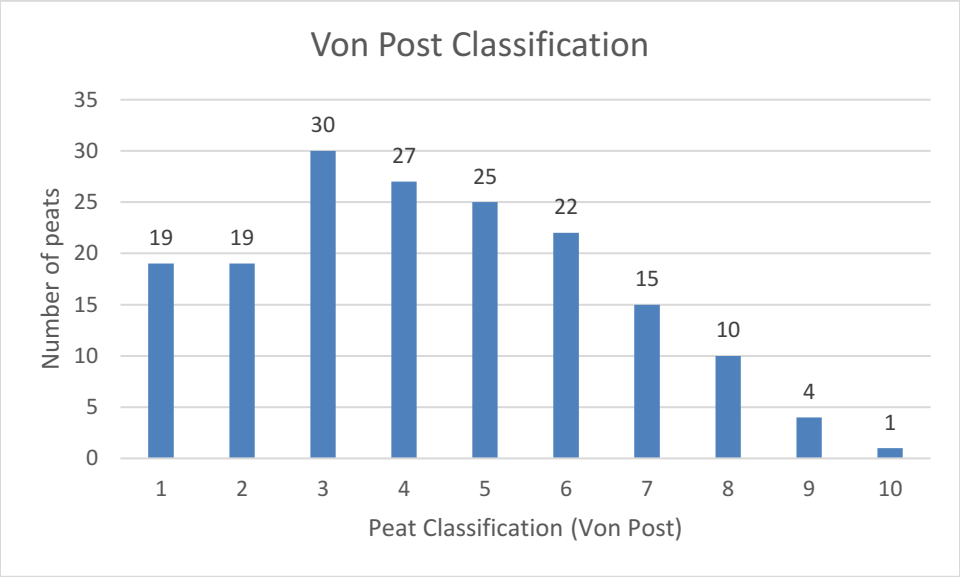

Figure 4 Distribution of Peat Classification

In situ shear strength testing was carried out at selected peat area locations using a handheld field vane. The Quebec Ministry of Transportation has adopted this field test as an acceptable approach when running stability analyses for organic soils, specifically those classified H5 to H10 (DLC, 2012). Readings were recorded every 0.5 m, when possible, and extended in the underlaying clay deposit when intercepted. Shear resistance values in average varied from 12 to 30 kPa indicating a soft to firm consistency. However, multiple tests yielded values under 5 kPa, indicating a very soft consistency.

The auger sampling at the peat areas extended to the underlaying mineral deposit. The type and consistency of the deposit has a direct incidence of the treatment method during construction works, but also plays a role in the global stability of the future rail embankment. The deeper soils at almost all investigated area were identified as clay or clayey silt with a consistency described as firm to very stiff, based on the vane readings. Toward the north end of the alignment, the soils under the peat transitions to a granular material (sandy silt to sand). Some peat areas have been labelled as sitting on a till deposit but none directly on bedrock.

Sampling and testing of the peat were not carried out as part of this terrain mapping investigation. For the feasibility study, the following general parameters for the peat, based on typical textbook values, can be considered for the preliminary design purposes of the future rail embankment.

- In areas with less than 0.5 m of peat, moisture content of 250%.
- In areas with more than 0.5 m of peat, moisture content between 500% and 1000%.
- Organic content of 95%.
- Unit weight of 9 to 11 kN/m^3
- Typical permeability range is between 1x10^{-6} et 1x10^{-3} cm/sec, depending on the decomposition state.

Where less than 0.5 m of peat was observed, it is anticipated that the deposit would have undergone significant drying due to exposure during summer months and would be similar to a peat crust.

Generally, fibrous organic material yield generally a higher moisture content than organics with advanced decomposition state (DLC, 2012).

It is stressed that the above textbook values are provided only as an indication of the potential compressibility of the soils and that a more detailed investigation will be required, including sampling and laboratory testing, to determine site specific characteristic parameter.

3.3 Subsurface Stratigraphy

The borehole records depict conditions at specific locations and on the dates indicated. Subsurface soil and groundwater conditions at locations away from the boreholes could vary from those indicated on the borehole reports.

It should be noted that the term "depth" always refers to the ground surface level during field work (mbgs) as defined previously in section 2.5.

The subsurface stratigraphy summary is presented in the following tables. Table 5 presents the boreholes drilled for the bridges/culverts, while Table 6 presents boreholes drilled for the high embankments. The subsurface conditions observed, and the results of the field and laboratory testing, are detailed in the borehole reports included in Appendix C.

Table 5 Subsurface Stratigraphy Summary – Bridges / Culverts

Kilometer Point (KP)	Description	Borehole	Stratigraphy (Depth, m)						
			Topsoil	Granular Fill	Peat / Organic Soils	Native Cohesive Deposit	Native Granular Deposit	Till	Bedrock

(1) Presence of boulders and/or cobbles.

(2) Inferred bedrock following a refusal during the dynamic cone penetration (BNQ 2501-145).

3.3.1 Topsoil

Topsoil was encountered at surface generally in all boreholes and was found to extend to a depth ranging from 0.05 m to 0.61 m below ground surface (mbgs).

3.3.2 Granular Fill

The granular fill was generally encountered on the shoulders, the ditch or gravel road sections around of the Billy Diamond Highway, at a depth ranging from 0.00 to 0.18 m below ground surface. This layer has a thickness ranging from 0.61 to 2.44 m and essentially consisted of a brown grey to brown, gravelly sand to gravel and sand, with some to traces of silt.

The presence of boulders and/or cobbles was observed within this layer at boreholes BH22-04 and BH22-18.

Twenty-two (22) representative samples of this granular fill were selected for grain size distribution. The laboratory results are presented in the following table and are included in Appendix D.

Table 7 Laboratory Results – Granular Fill

Borehole	Sample	Depth (m)	Fines (%)		Sand (%)	Gravel (%)
BH22-02	SS-01	0.00 – 0.61	8.6		61.7	29.7

BH22-27	SS-01	0.00 – 0.61	4.0		40.9	55.1
BH22-31	SS-01	0.00 – 0.61	9.5		41.9	48.9

Borehole	Sample	Depth (m)	Fines (%)	Sand (%)	Gravel (%)
BH22-32	SS-01	0.00 – 0.61	9.0	58.0	33.0
BH22-35	SS-01	0.00 – 0.61	8.0	45.2	46.8
BH22-38	SS-01	0.00 – 0.61	10.3	35.0	54.7
BH22-40	SS-01	0.00 – 0.61	8.7	50.8	40.5
BH22-43	SS-01	0.00 – 0.61	9.0	48.7	42.3

3.3.3 Peat / Organic Soil

An organic soil was encountered on boreholes BH22-11, BH22-13, BH22-31, BH22-36, BH22-39 and BH22-43, at a depth ranging from 0.00 to 2.44 m below ground surface (mbgs).

This layer of organic deposit had a thickness ranging from 0.10 m (at BH22-11) to 1.53 m (at BH22-31) and essentially consisted of peat, black organic soil with a presence of vegetal debris and roots.

3.3.4 Native Cohesive Deposit

With a few exceptions, a native cohesive deposit was encountered in all boreholes, at depths ranging from 0.10 m (at BH22-06) to 3.66 m (at BH22-31) (mbgs). This natural soil essentially consisted of a grey silty clay to a silt and clay with traces of sand and gravel.

Based on available geological mapping, the Billy Diamond Highway is mostly situated within the glaciolacustrine varved clay plains formed when the region was submerged by glacial Lake Barlow-Ojibway. Visually, varved clays consist of thin laminations, rarely exceeding 2 to 3 cm of light silty layers between dark clayey layers. Within the upper reaches of the alignment, Tyrrell Sea marine clays deposits may also be present. Generally, the Barlow-Ojibway varved clays are slightly over consolidated, soft to firm in consistency, with a high compression index.

Sixty-seven (67) representative samples of this native cohesive deposit were selected for hydrometer tests. The laboratory results are presented in the following table and are included in Appendix D.

Table 8 Grain Size Distribution from Hydrometer Tests - Native Cohesive Deposit

Borehole	Sample	Depth (m)	Fines (%)		Sand (%)	Gravel (%)
			Clay	Silt

The moisture contents obtained on representative samples of this native cohesive deposit range from 23.7% to 92.6%.

Nineteen (19) samples have moisture contents greater than the liquidity limit ($I_L \geq 1.0$), this means that the material could lose its plastic behavior and act as a liquid when excavated and reworked.

Eighteen (18) samples have moisture content lower than the liquidity limit ($0 \geq I_L \geq 1.0$), this means that the material could keep his plastic behavior when excavated and reworked.

Eleven (11) samples of the native cohesive deposit were selected for consolidation tests. The results are presented in the following table and are included in Appendix D.

Table 10 Consolidation Test Results – Native Cohesive Deposit

Borehole	Depth (m)	σ'_{v0} (kPa)	σ'_p (kPa)	OCR	Cr	Cc	Consolidation Condition

BH22-38	6.80 – 7.80	37 – 49	43	--	--

In-situ field vane shear tests conducted on this native cohesive deposit resulted in undrained shear strength values ranging from approximately 17 kPa to 111 kPa; the weaker, soft to very stiff soils were observed at shallow depths, and the strength of the clay gradually increased with depth such that the high value of 111 kPa was observed at a depth of 7.7 m.

Twenty-five (25) samples from the native cohesive deposit were selected for shear resistance with the Swedish fall cone tests. The shear resistance results are presented in the following table and are included in Appendix D.

Table 12 Swedish Fall Cone – Native Cohesive Deposit

Borehole	Sample	Depth (m)	Shear Resistance Intact Soil Cu (kPa)	Shear Resistance Remoulded Soil Cu_r (kPa)	Moisture Content (%)	Unit Weight (kN/m^3)

BH22-36	ST-13	9.14 – 9.75	80	11	32.0	19.0
BH22-38	ST-10	5.49 – 6.10	39	7.1	51.4	17.0
BH22-40	ST-08	4.27 – 4.88	54	14.4	27.7	18.5

The shear resistance tests in laboratory conducted on this native cohesive deposit resulted in undrained shear strength values ranging from approximately 3 kPa to 109 kPa; the weaker, very soft to very stiff soils were observed at shallow depths, and the strength of the clay gradually increased with depth such that the high value of 109 kPa was observed at a depth of 4.88 m to 5.49 m in BH22-20.

Borehole BH21-31 ended within this native cohesive deposit at 37.19 m below ground surface (mbgs).

3.3.5 Native Granular Deposit

A native granular deposit was encountered generally in all boreholes at a depth ranging from 0.05 m (at BH22-01) to 18.90 m (at BH22-24) below ground surface (mbgs). This natural granular deposit generally consisted of a grey silty and gravelly to some gravel sand with some to traces of clay.

Standard Penetration Test N-values measured in this natural soil deposit ranged between 2 to 63 indicated the soil is in very loose to very dense state with an average at 15 indicated a soil at compact state.

Twelve (12) representative samples of this native granular deposit were selected for grain size distribution tests. The laboratory results are presented in the following table and are included in Appendix D.

Table 13 Laboratory Test Results – Native Granular Deposit

Borehole	Sample	Depth (m)	Fines (%)		Sand (%)	Gravel (%)	USCS
			Clay	Silt			
BH22-04	SS-05	2.44 – 3.05	13.3	37.6	31.6	17.5	ML or MH
BH22-06	SS-23	18.28 – 18.90	5.8		85.9	8.3	SW
BH22-07	SS-04	3.66 – 4.27	12.9		67.2	19.9	SW
BH22-09	SS-13	11.28 – 11.89	1.5	89.6	8.9	0.0	ML or MH
BH22-13	SS-16	9.14 – 9.75	21.9		64.0	14.1	SM
BH22-15	SS-23	15.85 – 16.46	25.4		59.8	14.8	SM
BH22-20	SS-11	6.71 – 7.32	22.3	51.5	24.1	2.1	ML or MH
BH22-25	SS-18	10.97 – 11.58	2.5	24.2	50.7	22.6	SM
BH22-33	SS-03B	1.32 – 1.83	6.3	84.3	7.6	1.8	ML or MH
BH22-34	SS-24	16.76 – 17.37	14.6		83.1	2.3	SM
BH22-37	SS-04	2.44 – 3.05	31.6	30.5	37.6	0.3	ML or MH
BH22-42	SS-01B	0.05 – 0.61	6.0		20.1	73.9	GW

Boreholes BH22-06, BH22-09 BH22-15 and BH22-34 ended within this native granular deposit, at depth ranging from 17.98 m and 24.69 m below ground surface (mbgs).

3.3.6 Till

A native granular deposit was generally encountered in all boreholes at a depth ranging from 2.44 m to 19.81 m below ground surface (mbgs). This natural till deposit generally consisted of a grey silty gravelly sand to a silty sand with some gravel, with traces of clay.

Standard Penetration Test N-values measured in this natural soil deposit ranged between 3 to 100 indicated the soil is in a very loose to dense state.

Moreover, it is important to note that the till is naturally a heterogeneous deposit and that it may exhibit a significant degree of vertical and lateral variability in grain size distribution. It's likely that larger boulders and cobbles may be present in the deposit in greater quantities than in the boreholes used for this investigation.

Twenty-four (24) representative samples of this till deposit were selected for grain size distribution tests. The laboratory results are presented in the following table and are included in Appendix D.

Table 14 Laboratory Test Results – Till

Borehole	Sample	Depth (m)	Fines (%)		Sand (%)	Gravel (%)	USCS
			Clay	Silt			
BH22-01	SS-02	0.61 – 0.99	2.2	48.2	46.9	2.7	ML or MH

Borehole	Sample	Depth (m)	Fines (%)		Sand (%)	Gravel (%)	USCS
			Clay	Silt			
BH22-42	SS-08	4.27 – 4.88	23.9		48.8	27.3	SW
BH22-42	SS-14	7.92 – 8.53	21.9		69.1	9.0	SM

Boreholes BH22-11 to BH22-14, BH22-16, BH22-17, BH22-20 to BH22-22, BH22-24, BH22-25, BH22-28 to BH22-30, BH22-35 to BH22-37, BH22-41 and BH22-42 ended within this native till deposit, at depth ranging from 7.59 m and 28.04 m below ground surface (mbgs).

3.3.7 Bedrock

According to the *Système d'information géominière du Québec* (SIGEOM), the bedrock in the area is generally composed of sedimentary, metasedimentary, mafic and intermediate volcanic rocks (Basalt, andesite), tonalite, granodiorite, granite, and gneiss, all belonging to the Abitibi Subprovince, Opatica Subprovince, Nemiscau Subprovince and La Grande Subprovince group.

The bedrock was encountered in boreholes BH22-01 to BH22-05, BH22-07, BH22-08, BH22-10, BH22-18, BH22-26, BH22-27, BH22-32, BH22-33, BH22-38, BH22-39, BH22-40 and BH22-43, at depths ranging from 0.99 m to 16.46 m below ground surface (mbgs). The rock was confirmed by coring over a length that varies between 1.37 and 7.11 m. The recovery measured for the different sample varied between 30 and 100 %.

The bedrock samples recovered show that in these boreholes, the bedrock is identified as a grey sandstone in borehole BH22-01 to grey granite in borehole BH22-03 and BH22-43, a grey basalt in boreholes BH22-04 and BH22-07, grey rhyolite in BH22-05, grey monzonite in BH22-08 and grey gneiss in BH22-18, BH22-32 and BH22-38.

For a structural interpretation, the rock quality designation (RQD) was determined on the rock cores recovered during drilling. This value is an indirect assessment of the number of fractures in the rock mass. For all the rock cored in this preliminary geotechnical investigation, the measured value of the RQD varies between 21 and 100 %, corresponding to very poor quality at surface to average quality at greater depths. The various RQD values measured appear to indicate that the rock is of average quality, with an average RQD of about 60%.

Eleven (11) uniaxial compressive strength and density tests were performed on representative bedrock samples. The results are presented in the following table and are included in Appendix D:

Table 15 Laboratory Test Results – Bedrock

Borehole	Sample	Description	Depth (m)	Volumic Weight (kg/m^3)	Unit Weight (kN/m^3)	Compressive Strenght (MPa)	Classification (ISRM, 1981)
BH22-01	DC-03	Sandstone	1.36 – 1.48	2770	27.2	110.1	R5 – Very strong

Borehole	Sample	Description	Depth (m)	Volumic Weight (kg/m^3)	Unit Weight (kN/m^3)	Compressive Strenght (MPa)	Classification (ISRM, 1981)
BH22-03	DC-06	Granit	3.03 – 3.15	2676	26.3	175.4	R5 – Very strong
BH22-04	DC-09	Basalt	4.97 – 5.02	2851	28.1	95.2	R4 – Strong
BH22-05	DC-15	Rhyolite	9.05 – 9.17	2758	27.1	264.6	R6 – Extremely strong
BH22-07	DC-05	Basalt	5.44 – 5.56	3127	30.7	48.9	R3 – Medium strong
BH22-08	DC-14	Monzonite	9.90 – 10.02	2809	27.8	177.3	R5 – Very strong
BH22-10	DC-13	Granit	7.18 – 7.30	2570	25.2	189.1	R5 – Very strong
BH22-18	DC-18	Gneiss	16.06 – 16.18	2645	25.9	146.8	R5 – Very strong
BH22-32	DC-13	Gneiss	8.05 – 8.17	2800	27.5	124.9	R5 – Very strong
BH22-38	DC-18	Gneiss	15.80 – 15.92	2721	26.7	98.7	R4 - Strong
BH22-43	DC-08	Granit	4.83 – 4.95	2690	26.4	176.3	R5 – Very Strong

Boreholes BH22-01 to BH22-05, BH22-07, BH22-08, BH22-10, BH22-18, BH22-26, BH22-27, BH22-32, BH22-33, BH22-38, BH22-39, BH22-40 and BH22-43 ended at depths ranging from 2.51 and 17.81 m below ground surface.

3.4 Groundwater

The depth to the groundwater level was measured in boreholes BH22-06, BH22-09, BH22-14, BH22-15, BH22-24, BH22-27, BH22-28, BH22-29, BH22-30, BH22-33, and BH22-37 and are presented in the following table.

Table 16 Groundwater Levels

Borehole	Groundwater Level (m)	Date
BH22-06	0.00	18/10/2022
BH22-09	1.86	09/11/2022
BH22-14	0.55	02/11/2022
BH22-15	0.30	17/10/2022
BH22-24	0.00	17/10/2022

Borehole	Groundwater Level (m)	Date
BH22-27	0.70	17/10/2022
BH22-28	4.25	04/11/2022
BH22-29	2.37	17/10/2022
BH22-30	0.00	17/10/2022
BH22-33	0.66	05/11/2022
BH22-37	0.00	10/10/2022

Groundwater levels can be expected to fluctuate during periods of heavy precipitation associated with seasonal weather trends, or particular events, site use, adjacent site use, and construction activity. Therefore, it is possible that the groundwater will be different during the planned work.

4.0 Discussions and Recommendations

This section provides general guidance related to the geotechnical design aspects of the construction of the potential Billy-Diamond Highway railway, based on our interpretation of the available subsurface information described herein, and our understanding of the project requirements.

The discussion and recommendations presented in the following sections are to provide the designers with functional information for planning and preliminary design purposes only. A detailed geotechnical investigation and design report, complete with additional boreholes, will be required prior to or during the final design stage of the project.

4.1 Project Summary

The project consists of the design, development and construction of a new railway that will extend from the town of Matagami at south (KP 0) to the Rupert River at north (KP 253).

The potential BDH railway alignment closely follows the actual alignment of the Billy-Diamond Highway and deviates from it a maximum distance of 4 km in some localized sectors. The railway will be built on mineral and organic soils, in forested and undeveloped areas. A significant part of the railway, approximately 20% of the alignment, will be built on peat; these areas will require a special geotechnical attention during the next design phases.

Bridges and culverts will be built along the alignment to cross rivers and streams, as well as the Billy-Diamond Highway at some locations. The geodetic elevations range from el. ≈290 m at Matagami to el. ≈190 m at the Rupert River Bridge. Several high embankments are also anticipated throughout the proposed alignment.

The preliminary geotechnical investigation was carried out to estimate the baseline *in-situ* conditions at the Site that will influence the Feasibility Study for the construction of the potential BDH railway. The following sections outline the geotechnical and material concerns and requirements that will influence the feasibility and the design of the project.

This report discusses construction design methods which may be considered for the preliminary design of the railway, while referring to certain typical concepts applicable to road infrastructures in a northern environment and reflecting the subsurface conditions encountered during the present investigation (presence of fine compressible soils and large areas of organic soils/peat). It provides guidance to the designer in modifying or amending current practices, considering the specific context of the project. A list of relevant elements to consider when selecting the design and construction methods and carrying out a preliminary design is also provided. Finally, recommendations are made to carry out additional and detailed geotechnical studies in specific areas or structure locations.

4.2 Roadbed Construction

4.2.1 General

Section 4.2 discusses issues which will need to be evaluated as part of the design of cuts and fills along the railroad alignment. The roadbed, which will support the sub-ballast and ballast layers, is referred to as the *top of subgrade*.

Where fill is required to raise the ground surface to the proposed top of subgrade, this report refers to the materials required to raise the grade as *embankment fill* which are constructed over the existing *foundation soils.* In fill sections, the top of subgrade will consist of embankment fills, and in cut sections, of foundation soils.

Over 20% of the project alignment crosses areas consisting of peat deposits. The treatment of peat areas is discussed separately in *Section 4.3: Special Considerations for Peat Treatment*.

Most of the project alignment extends the Barlow-Ojibway varved clay plains which are normally to slightly over consolidated, soft to firm in consistency, with a high compression index. The stability of roadbed embankments in clay soils is discussed separately in *Section 4.4: Stability Analysis of Embankments*.

4.2.1.1 Assumed Cross-Section

Design cross-sections will need to be developed as part of the detail design stages. The discussions in this report generally assume the following in fill and cut sections.

- Embankment foreslopes (in fill areas) and ditch foreslopes (in cut areas), to the left and right of the tracks, will be no steeper than 2H:1V but could be flatter to accommodate geotechnical issues.
- Where ditches are required, they would be at least 3.0 m wide at the base but could be wider if deemed necessary to accommodate hydraulics.
- Where ditches are required, the bottom of the ditch would be at least 1.0 m below the bottom of the ballast but could be deeper to accommodate hydraulics.
- Within soil cut areas, the backslope located between the outer ditch line and the natural ground will be no steeper than 2H:1V but could be flatter to accommodate geotechnical issues.
- Within rock cut areas that are less than 6 m in height, the backslopes in sedimentary rock will be 2.5V:1H and 10V:1H in other rock types.
- Within rock cut areas, at detail design it could be determined that a wider ditch is required in some areas to act as a rock catchment area to contain potential rock fall without impeding the hydraulic function of the ditch.
- That interceptor ditches will be constructed above cut slope to prevent surface water runoff from entering the cut areas.

4.2.1.2 Frost Penetration

Based on available information, the mean freezing index along the alignment range from about 2100 to 2200 mean Degree-Days below 0°C, which corresponds to a frost penetration depth of approximately 3.0 m. The AREMA manual suggests that in areas with frost heave problems, a frost treatment depth of 60% of the frost penetration should be used for soil replacement, which would correspond to 1.8 m.

As a preliminary design strategy, except in areas where the roadbed consists of bedrock or a well-grade sand with a USCS symbol of SW, it is recommended that the rail embankment be designed to ensure a minimum vertical height of 1.8 m from the bottom of the ballast to the top of the natural foundation soil. For most soil types, this will ensure that the total seasonal frost heave will be less than 75 mm. The embankment fills placed between the sub-ballast and the natural foundation soil should consist of a soil containing less than 30% silt and clay size particles, commonly referred to as a coarse-SM soil.

In areas where the natural foundation soils consist of clays (CH) or silts (ML), significantly greater frost heave would be anticipated, even when using a frost treatment depth of 1.8 m. The following provides an estimate of anticipated frost heaves when using a 1.8 m frost treatment depth for various soil types encountered along the alignment.

- For soils where the natural foundation soils are designated as SM (silty sands), frost heaving in the order of 50 mm to 75 mm would be expected.
- In the case where the natural foundations soils have been designated as ML (silt and sandy silt), frost heaves in the order of 150 mm would be expected.
- In the case where the natural foundation soils have been designated as CH (clays), frost heaves in the order of up to 300 m would be expected.

Where subgrade transitions are anticipated between ML or CL soil types and other soil types, a frost treatment depth of 2.5 m is recommended, with the limits of the tapered excavations selected based on AREMA Section 1.4.1.7.4: Replacement of Frost-Heaving Material.

As part of the final design, the frost heave tolerances should be reviewed for the rail project. The recommended global frost treatment depth for the project should be selected based on this review.

4.2.1.3 Reuse of Site **Generate** *Soils*

Once the final rail profile has been established, the volumes of potential fill materials should be evaluated. The following soil types should be excluded when assessing the volumes of potential fill materials.

- The native cohesive deposits described as silty clays, and as silt and clay soil, assigned a USCL group symbols of CL and CH, are not considered suitable for reuse. These soils are excessively wet and are not considered compactable for the construction of the embankment fills.
- Organic soils such as peat are also not considered suitable for reuse.

For the construction of embankment fill material to be placed within 1.8 m of the underside of the railway ballast, it should be limited to soils containing less than 30% fine particles (silt and clay size particles) or rock fill materials.

For the construction of embankment fill materials placed lower than 1.8 m below the underside of the railway ballast, all soil types, excluding the silty clays, the silt and clays, and the organic soils are considered suitable.

4.2.2 Natural Foundation Soils

Prior to placement of embankment fill or railway structure (ballast and sub-ballast), the natural foundation soil should be prepared to ensure adequate drainage and to provide sufficient bearing capacity to offer an acceptable factor of safety against the loads that will be imposed by the tracks. In addition, the embankment fill should be designed and constructed to tolerate the settlements associated with the compression of the natural foundation soils. Based on consolidation test results presented in Table 10, it is anticipated, depending on the specific site location, that primarly consolidation settlements within the clay deposits will be initiate once 1 to 2 m of embankment fill is place. Once the profile height has been confirmed, it is recommended that settlement calculations be undertaken to assess the magnitudes of settlements anticipated.

As part of the preliminary design considerations, the following general soil removal should be anticipated when preparing the subgrade.

- Where less than 2.0 m of embankment fill material is to be placed, organic soils and peats should be removed (this is discussed further below).

- Except where peat treatments are proposed, such as discussed in Section 4.3, topsoil, peat thicknesses of less than 1.0 m, and other organic layers, should be stripped from beneath the proposed embankment fill.

- Silty clays, and silt and clay soils within 1.8 m of the underside of the ballast should be removed and replaced with a soil containing less than 30% fine particles or with rockfill.

- Locally soft or wet soils that cannot be compacted to 90% of its optimum dry density as defined by the modified Proctor test should be removed. In this case, the soft soils should be subexcavated and replaced with a compacted fill containing less than 30% fine particles.

- Large areas of soft and wet soils could be treated using geosynthetics (geogrids, geotextiles and geocells) to replace potential subexavation and replacement works. The potential for this application should be assessed as part of the detail design.

Where the natural foundation soils consist of silty clay, or silt and clay (cohesive deposits), special construction techniques may be required to ensure that the embankment fill is stable, both during and after construction, and that the post construction settlements are tolerable. The following construction methods are anticipated.

- In the case tall fills over 3 m, it may be necessary to construct the embankment in stages to avoid overstressing the underlying cohesive soils. Once the embankment heights have been determined, the potential requirement to construct the embankments in stages will need to be evaluated by a geotechnical engineer.

- Depending on the settlement objectives and the proposed embankment heights, preloading and surcharging the site may be required prior to track construction to limit post construction settlements.

The study area includes natural foundation soils consisting of soft compressible fine soils and organic deposits directly underlain by fine compressible soils. It is anticipated that these soils will not be suitable to directly support construction traffic and that a separation barrier should be placed in these areas prior to construction of the embankment fill to prevent soil pumping and disturbance of the natural foundation soil during the construction process. Accordingly, it is recommended that a geotextile be placed on the natural foundation soil in areas where organic soils are to be removed and/or in areas where soft clay (silty clay, silt and clay soil) are present.

It is also suggested that the initial layer of embankment fill be at least 600 mm thick to protect the natural foundation soils, particularly when the embankment is placed on soft soils or on organic soils to prevent the instability of the natural foundation soils; the treatment of peat areas is discussed in Section 4.3. Where the embankment is constructed of rockfill or on peats, the initial layer would be increased to 900 mm (see sections 4.2.5 and 4.3.4).

In all cases, embankment slopes should not be steeper than 2H:1V to ensure the stability of the embankments throughout the construction period and the lifetime of the infrastructure. If slopes steeper than the latter are considered, stability studies should be performed to ensure their short- and long-term stability. Stability analyses that will be performed for every high embankment may imply that a flatter slope at the embankment is required.

4.2.3 Organic Soils

In general, vegetation, topsoil and organic soils should be removed to ensure an appropriate contact between the foundation soils and the embankment fill. The removed organic soils can be stockpiled and reused for landscaping purposes if deemed appropriate; it is noted that an assessment of potential topsoil recovery has not been carried out as part this study.

The excavation of organic soils is not required if more than 2 m of granular fill (including the granular structure of the railway) is anticipated. In cases where the embankment fill is thinner, it should be assumed that the organic soils will be completely excavated.

Where the rail alignment crosses peat areas, the treatment of these soils will require specific investigations. Section 4.3 of this report presents a preliminary analysis of potential treatment methods.

4.2.4 Geogrids

As part of the final design, the use of geogrids should be considered in peat areas where the peat is to remain in place. The use of geogrids is recommended in the following cases:

- Peat deposits which do not have an intact fibrous crust.
- Ditch crossings.
- Culvert transitions.
- Peat deposits with open water.
- Peat surfaces with ruts due to the passage of heavy machinery (ex.: presence of old logging sites in some peatlands of the alignment).
- Initial layer of fill constructed with material other than MG 112, MG 20 (e.g.: rock fill of controlled caliber).

The extended use of geogrids over the entire fill on organic soils is not required. Geogrids will not improve the total capacity of the embankment and will not prevent failure if the control of the thickness of the initial layer is not properly performed.

4.2.5 Fill Construction

Embankment fills will be built in areas where the rail bed must be raised to its final elevation. The composition of the embankment itself and the native foundation soils are the two main components that must be considered for the design of embankments (except high embankments). The geotechnical constraints should be considered when determining the embankment geometry and its material composition.

- Embankment fills must be designed to be fully stable under their own weight and future track loads. Much of the alignment crosses generally weak varved clay deposits which can be prone to global instabilities under tall or over-steep embankments.

- Embankment designs must also consider anticipated settlements. As presented in Section 3.3.4, the clays underlying the site are frequently normally or over-consolidated and are highly compressible.

- The design frost penetration depth in this area is 3.0 m. To limit frost related differential movements, all embankment fill within 1.8 m of the bottom of ballast should consist of soils containing less than 30% fine particles or consist of rockfill.

As much as possible, the embankment fills should be constructed using excavated materials from cut sections and ditch excavations. Since the clayey soils are not considered suitable for reuse, it is likely that the required quantities will be greater than those anticipated for the excavation. It is anticipated that manufactured or imported materials from borrow pits or quarries will be required.

It is also suggested that the initial layer of embankment fill be at least 600 mm thick to protect the natural foundation soils, particularly when the embankment is placed on soft soils or on organic soils (peatlands) to prevent the instability of the natural foundation soils.

For excavated materials to be considered reusable, it must have a water content that facilitates compaction and be free of organic soils; for this reason, the clay soils encountered along the project length are not considered suitable for the construction of embankment fill.

Where fill is to be used behind retaining structures, free-draining backfill materials such as MG-20, MG-56 or CR-14 should be used within a granular wedge extending up from the base of the wall at a slope of 1H:1V.

The construction of embankments must include continuous inspection and testing to ensure that proper fill materials are use and that they are adequately compacted.

Considering the northern context of the Site, a certain flexibility regarding the choice of granular materials may be required. It will be necessary to consider the availability of these materials and the necessary effort to obtain the required grain-size distribution and normally required aggregate physical properties (crushing, screening, transportation, stockpiling, etc.). Available material sources should be reviewed as part of the detail design.

Section 1.2.3.4 of the AREMA outlines specific requirements for the construction of rockfill that could be used as an alternative to mineral soils or granular materials. This option could be considered for reasons of cost/or availability of materials in northern areas. Rockfill will tend to cause long-term settlement due to the gradual compaction of the fill itself. In areas where long-term settlement will not be tolerated, the use of borrow pits materials should be preferred for the construction of the fill. Rockfill should be used primarily in areas where settlement can be corrected, and the surface easily reshaped. The design of rockfill and the establishment of project-specific requirements should be carried out by a geotechnical engineer experienced in the construction of rock fill, taking into account the project-specific conditions (presence of peats areas and fine compressive soils). Where the embankment is constructed of rockfill, the initial layer would be increased to 900 mm.

A balance factor should be calculated in subsequent stages of this project. This factor must consider the following in addition to the total volume of cut and fill to be placed:

- General thickness of organic soils on alignment.
- Average thickness of organic soils in peat areas.
- Anticipated settlement of organic soils and mineral soils beneath the embankments (including high embankments) which will increase the required volume of embankment fill.
- The non-suitable nature of the clay soils due to its wet state.
- Potential reuse of the till soils.
- Presence of boulders.
- Densification of embankment fill materials during placement.

- Anticipated loss of material during transportation and temporary storage.

Based on the Atterberg limits test results carried out on the clay samples, approximately half of the samples had a liquid content above the liquid limit when tested in the laboratory (liquidity index greater than or equal to 1). This implies that the soft clay soils present in the study site could lose their plastic behavior when handled and transported and become difficult to dispose of.

4.2.6 High Embankments

Railway embankments over 4 m in height were considered as "high embankments". A preliminary list of high embankments was provided by the project design team to validate the geotechnical parameters in place at each of these areas. The soil conditions at each of the boreholes drilled in the identified high embankment areas are presented in Table 6 in Section 3.3. Of the 18 high embankment areas identified, nine (9) include embankments of 6 m height or more, and two (2) include embankments of 10 m or more.

According to AREMA, embankments should be designed to account for settlements and to prevent failure of the underlying soils. As previously indicated, where clay deposits have been identified, the natural foundation soils are highly compressible and weak. Potential treatment or soil improvement methods for these areas are discussed further below. Future investigations in the high embankment areas may identify different ground improvement methods to be considered, depending on the soil conditions encountered in future investigations.

In areas with granular or dense soils, or with shallow bedrock, the use of ground improvement methods is not anticipated. Future investigations and analysis in these areas will also be required to confirm the geotechnical parameters to be used to model the behaviour of the natural foundation soils beneath the proposed high embankments.

In the context of the feasibility study, only one borehole was drilled for each high embankment area, which can extend over several hundred meters. The number of boreholes, depth, and in-situ tests to be performed for complementary investigations must be sufficient to provide a reliable representation of the full length of the high embankment area, including the natural foundation soils beneath potential embankment berms, where required. The future investigations in high embankment areas underlain by clay will need to identify construction staging requirements, where applicable.

Each high embankment area should be subjected to a stability and settlement analysis to ensure the stability of the future railway platform. The analysis must consider settlements of the underlying organic soils (when left in place) and the mineral soils. According to AREMA the following should be checked.

- The stability of the embankment under its own weight and imposed loads.
- The stability of the embankment and natural foundation soils system in combination.
- An economic tolerance on the magnitude of anticipated settlement.

For the design of a railway embankment, a safety factor of 1.5 is generally considered adequate. However, if the engineer performing the stability analyses has sufficient information for the analyses, a

smaller safety factor could be considered. If field and laboratory data are inconsistent or inadequate, the engineer should consider increasing the factor safety factor.

In case the required factor of safety cannot be reached, or where settlements are considered excessive, one or more of the soil improvement methods listed in the AREMA can be considered:

- Replacing unsuitable foundation soils with compacted structural fill.
- Flattening embankment slopes or adding berms at the toes of the embankment.
- Installation of a foundation drainage system to reduce pore water pressures.
- Construction of the embankment in several stages.
- Densification of granular foundation soils, where possible.
- Use of light embankment materials (fill).
- Mechanical reinforcement of foundation soils and/or embankment.
- Preloading and surcharging the fill areas to accelerate consolidation of organic or cohesive soils.
- Installation of retaining walls.

It should be anticipated that combinations of these soil improvement methods will be required in all areas identified as high embankment areas where the natural foundation soils consist of clay.

4.2.7 Cuts

Deep cuts (greater than 5 m) must be analyzed in detail and a stability study must be carried out for the final design. For the present feasibility study, it is assumed that no deep cuts will be required within areas underlain by clays; if deep cuts are proposed in the clay deposits, these will require boreholes specifically at those locations to identify a safe slope profile.

Generally, excluding the clay soils, cut slopes of 2H:1V can be considered for the feasibility study for the soils encountered at the site. This assumes that adequate ditch drainage will be provided at the toe of slope and that interceptor drains will be constructed at the top of slopes. Should the detail investigations to be carried at the later stages of the project identify a risk that groundwater could emerge from the face of the slope, special treatments such the placement of granular drainage layer, construction of drainage buttresses, or the installation of toe drains could be considered.

In areas with clay deposits, silt deposits or with unfavourable groundwater conditions, flatter slopes may be required. This would ultimately increase the volume of soils and widen the overall width of the railway construction zone.

For all soil types, it is essential to maintain stable and safe permanent cut slopes. The width of the cut area should be sufficient for the installation of ditches at the bottom of the slope to collect resurging groundwater. In some areas, the results of the stability analyses may justify that the cut slope be benched, or that other measures such as additional drainage systems, erosion protection or filter layers, and revegetation be applied.

Where the factors of safety obtained from the slope stability analyses do not provide a safe geometry, the use of retaining walls could be also considered if the other cost-effective alternatives mentioned above cannot be achieved.

For the design of all cut areas, Article 1.2.2 of the AREMA manual should be consulted. It outlines the essential components and features to be considered in the preparation and design of soil and rock cut areas. It includes factors that may affect the depth of excavations and provides general recommendations for the design and geometry of cut slopes.

4.3 Special Considerations for Peat Treatment

4.3.1 General Considerations

As previously discussed, over 50 km of the rail alignment will be constructed on peat areas, representing approximately 20% of the alignment. The results of the preliminary terrain mapping indicates that 120 distinct peat areas are anticipated along railway alignment. Test holes were advanced at each of the identified peat areas to provide a preliminary summary of the organic soil characteristics which are presented Section 3.2.

Since there is no guide for the construction of railway embankments on peat deposits, the " *Guide pour l'étude et la construction de remblais routiers sur tourbières, DLC 2012* ", published by the *Ministère du transport du Québec*, was used as a guideline, with some aspects adapted to meet the railway's specific conditions and requirements. The geotechnical and railway engineers must maintain a critical mindset and use their best judgement regarding the applicability of the concepts proposed in this guide during the subsequent phases. Discussions should be held to assess the suitability of the methods proposed in this report and to share a part of knowledge with the ministry that considers the experience of the ministry with road projects in similar conditions and environments.

It is noted that, within the framework of the feasibility study, the frequency of surveys and tests conducted on the site provide only a partial understanding on the nature of the peat and its thickness, which is insufficient for the final design. The following discussions are general and discuss the treatment methods for peat areas that could be applied.

4.3.2 Peatland Treatment Methods

For this project, three (3) general methods of organic soil treatment in peat areas can be considered.

- Excavation.
- Traditional embankment (variable initial layer).
- Consolidation (with or without surcharge).

Each of these methods and their associated requirements are briefly described in the following sections. The choice of the treatment method should consider, among other factors, the nature of the infrastructure to be built, the extent and frequency of peat areas, the homogeneity of the organic layer and its thickness, the characteristics of the organic soils, the thickness of the embankment to be built, the nature of the

underlying mineral soils, the construction timeframe, and, lastly, the availability and nature of fill materials to be used.

4.3.2.1 Excavation

This method consists of completely excavating the organic soils over the entire extent of the peat area. This method is generally applied when the organic soils are thin (less than 2 m) and when the height of the embankment to be constructed is less than 2 m. It must also consider the nature of the underlying mineral soils, which must have a better bearing capacity than organic soils. In some cases, it may be more advantageous to slightly raise the profile to avoid the excavation of the organic layer. For the preliminary design, removal of the peat layer should be assumed when the following conditions are met.

- Embankment height less than 2 m.
- Thickness of organic soils less than 2 m.
- Bearing capacity of mineral soils greater than organic soils.

4.3.2.2 Traditional Fill (variable initial layer)

This method consists of constructing the embankment in a conventional manner, without considering the organic layer. It's therefore not necessary to have an instrumentation programme. Traditional fill is typically used for uniform deposits where the thickness of organic soils is less than 1 m and the height of the embankment to be built is greater than 2 m, to ensure the best consolidation of the organic soils.

For preliminary design, it should be anticipated that the peat material would compress by at least 50% of its initial thickness and that the estimated fill volume would need to consider additional materials to compensate for the compression.

The initial layer of the fill should be 600 mm thick if the organic soils are less than 0.5 m thick, and 900 mm thick if the organic soils are between 0.5 and 1 m thick.

- Embankment height greater than 2 m.
- Thickness of organic soils less than 0.5 m (initial layer of 600 mm).
- Thickness of organic soils between 0.5 and 1 m (initial layer of 900 mm).

4.3.2.3 Consolidation (with or without surcharging)

The consolidation method of construction consists of provoking a gradual settlement of the organic deposit, while avoiding any shear failure. It is mainly recommended when the thickness of the organic deposit is uniform and more particularly when there is no pavement, and the profile can be easily corrected following post-construction settlements. It can also be considered when the bearing capacity of the organic or mineral soils is insufficient for the embankment loads. This method is usually used when the organic soils are thicker than 1 m and the embankment height is higher than 2 m. If the embankment is less than 4 m, a surcharge should be applied.

- Embankment height greater than 2 m.
- Thickness of organic soils greater than 1.0 m and less than 4 m (with surcharge).
- Thickness of organic soils greater than 4 m (without surcharge).

A surcharge usually extends at least 600 mm above the finished ballast height, consisting of a granular material that is temporarily installed for a minimum period of 120 days. It may be preferable to construct the embankment fill with the surcharge before winter and leave it in place for the entire cold season. Depending on the settlement objectives, the surcharge height and the settlement period should be determined at the final design stages.

This construction method requires a rigorous monitoring of the settlements throughout the construction period. Therefore, an adequate instrumentation should be installed prior to the construction phase to constantly monitor the settlement progression during the process of construction. The instrumentation should include, but not be limited to, settlement points set in different layer, surface settlement points, and piezometers and lateral displacement indicators in the case where the peat is also underlain by compressible clay soils.

In all cases, the embankment should be constructed as described in Section 4.3.4 below.

4.3.3 Applicable Peat Treatment Method

An approximate list of peat areas along the alignment, and the height of embankment to be constructed was provided by the consultant. The recommended peat treatment methods for each area, based on the previous mentioned methods, are presented in the table below.

Table 17 Recommended Peat Treatment Method

Peat Zone Number	Location (m)	Thickness of Organic Soils (m)	Fill		Recommended Method
			Maximum (m)	Mean (m)	
1	0 to 1+600	0.3	3.9	1.3	Traditional Fill - 600 mm
2	1+600 to 3+600	0.5	13.0	8.9	Traditional Fill - 900 mm
3	3+600 to 4+200	0.3	0.5	0.5	Excavation
4	4+200 to 6+800	0.5	2.5	1.3	Excavation
5	6+800 to 9+200	0.3	14.8	4.2	Traditional Fill - 600 mm
6	9+200 to 13+100	0.5	10.7	2.0	Traditional Fill - 900 mm
7	13+100 to 13+600	0.3	-	-	Excavation
8	13+600 to 13+900	0.8	-	-	Excavation
9	13+900 to 17+500	0.3	13.7	1.3	Traditional Fill - 600 mm
10	17+500 to 17+700	0.9	-	-	Excavation

Peat Zone Number	Location (m)	Thickness of Organic Soils (m)	Fill		Recommended Method
			Maximum (m)	Mean (m)	
11	17+700 to 18+700	0.3	7.7	5.4	Traditional Fill - 600 mm
12	18+700 to 19+000	0.7	-	-	Excavation
13	19+000 to 29+000	0.3	11.9	3.7	Traditional Fill - 600 mm
14	29+000 to 29+400	0.5	1.1	0.9	Excavation
15	29+400 to 33+400	0.3	6.4	2.4	Traditional Fill - 600 mm
16	33+400 to 34+400	1.8	-	-	Excavation
17	34+400 to 55+600	0.3	14.7	3.9	Traditional Fill - 600 mm
18	55+600 to 58+000	0.5	3.8	1.5	Traditional Fill - 900 mm
19	58+000 to 59+500	1	1.3	1.2	Excavation
20	59+500 to 62+000	0.5	1.2	0.7	Excavation
21	62+000 to 66+000	0.3	2.3	1.3	Excavation
22	66+000 to 68+800	0.7	7.5	1.5	Traditional Fill - 900 mm
23	68+800 to 92+300	0.3	15.5	3.1	Traditional Fill - 600 mm
24	92+300 to 94+300	2.7	3.8	3.0	Consolidation with surcharge
25	94+300 to 104+300	0.5	16.8	3.3	Traditional Fill - 900 mm
26	104+300 to 123+000	0.3	8.3	2.4	Traditional Fill - 600 mm
27	123+000 to 123+600	0.8	2.3	0.7	Excavation
28	123+600 to 135+800	0.3	16.2	4.2	Traditional Fill - 600 mm
29	135+800 to 136+300	1	3.0	1.5	Excavation
30	136+300 to 138+800	0.5	9.4	4.0	Traditional Fill - 900 mm
31	138+800 to 139+600	1.5	1.3	0.4	Excavation
32	139+600 to 140+500	0.3	1.8	0.7	Excavation
33	140+500 to 141+200	0.6	1.3	0.5	Excavation
34	141+200 to 143+000	0.3	1.4	0.4	Excavation
35	143+000 to 144+800	0.5	8.0	1.7	Traditional Fill - 900 mm
36	144+800 to 149+400	0.7	5.8	2.8	Traditional Fill - 900 mm

4.3.4 Fill Construction on Organic Soils

Regardless of the treatment method chosen for construction on peat, all embankments should be constructed using the same procedure.

The initial layer of embankment laid on organic soils should be composed of granular material, generally sand, type MG 112. To avoid punching of the organic soils, the material shall not contain cobbles with a diameter exceeding 100 mm. This first layer will be 900 mm thick, except in the case of a traditional fill treatment with a 600 mm initial layer (see Section 4.3.3).

In the case where it would be difficult to obtain granular materials of type MG 112, the initial layer of fill should be constructed with a rock fill, the size and grading of the material must be approved in advance. In such a case, the installation of a geotextile and a geogrid is recommended before placement of the initial lift embankment fill.

Controlling the thickness of the initial layer will be of primary importance to the performance of construction operations on peat. Throughout the construction of the initial layer, constant monitoring will be required to identify any areas that are not performing as anticipated. The feasibility of the peat construction methods is critically dependent on the quality of the placement of the initial layer; the final design should determine restrictions on the weight of the equipment used, the spacing and loading of haul trucks and construction vehicles, and the recommended waiting periods between each layer to be followed.

Once the initial layer of embankment fill is in place, the other layers of embankment can be constructed within a time delay determined by the dissipation of pore pressures and the consolidation of the deposit, according to the piezometers and settlement indicators installed.

The completion of the embankment can be done with successive layers of 300 mm thick, compacted with a bulldozer. Between each of the layers, a time delay will be necessary, the time of which will be determined in accordance with the readings recorded by the piezometers. If no piezometers are installed, the normal time delay in days between layers can be estimated at 2.5% of the thickness of the last layer laid, or approximately one week for a 300 mm layer.

Finally, where a surcharge is to be placed to accelerate the consolidation, it should be built to its full height over the entire peat area to be consolidated by surcharge, and it should be tapered progressively with a longitudinal slope of 1V:25H over the embankment in the areas without surcharge. The surcharge should be left in place until a geotechnical engineer confirms, based on the settlement monitoring data, that the compression objectives have been met, a minimum period of 120 days is recommended before removing the granular surcharge.

Given the significant extent of peat treatment anticipated for this project, it is recommended that a properly prepared work plan that meets all the requirements established during the next engineering phases be approved by a geotechnical engineer in charge of the project and by the client. Full-time supervision should then be maintained to ensure that construction and peat consolidation operations are carried out properly.

4.3.5 Settlements in Peats

The consolidation and settlement mechanism of organic soils occurs in two stages, the consolidation of the macroscopic system first, followed by the consolidation of the microscopic system. These two consolidations occur simultaneously, and the settlement curve will be largely influenced by the rate of loading. Secondary settlements will be associated with consolidation of the microscopic void system corresponding to the retained water in the organic soil fibers. Post-construction secondary settlements can therefore be quite long and will depend on the applied loading. The use of drains will increase the dissipation of macroscopic voids and therefore primary settlements but will not greatly affect secondary settlements.

To estimate the additional quantities of material required to achieve the desired profile, it is necessary to anticipate the settlements generated by the placement of the embankments. In addition to the settlements caused by the organic soils (primary and secondary settlements), it will also be necessary to consider the settlements of the underlying mineral soil layer, especially in the case of soft and compressible fine soils (clay). Settlement analyses must be performed in subsequent phases of the project.

Figure 5 below, obtained from the "Guide" of MTQ, can be used to estimate the total thickness of material required to achieve the desired grade for the intended profile, according to the following equation.

It is to be noted that this estimation method is relatively reliable for embankments 1.2 to 2 m thick (accuracy ± 20%) but the accuracy tends to decrease with the increase of the embankment height. For

embankments 1.2 to 2 m thick, in theory, settlements will generally not exceed 50% of the organic layer thickness. Under higher embankments, settlements may be of higher magnitude. This curve should be used only for the purpose of estimating the additional quantities of material required to achieve the final profiles. It should not be used during construction to monitor settlements (use the instrumentation program during construction).

$$Rt = Hr * 100/(100-T)$$

Where:

Rt = total height of the embankment to be constructed.

Hr = expected height above the natural ground surface to reach the fixed level (with or without surcharge).

T = Percentage of expected settlement according to the curve.

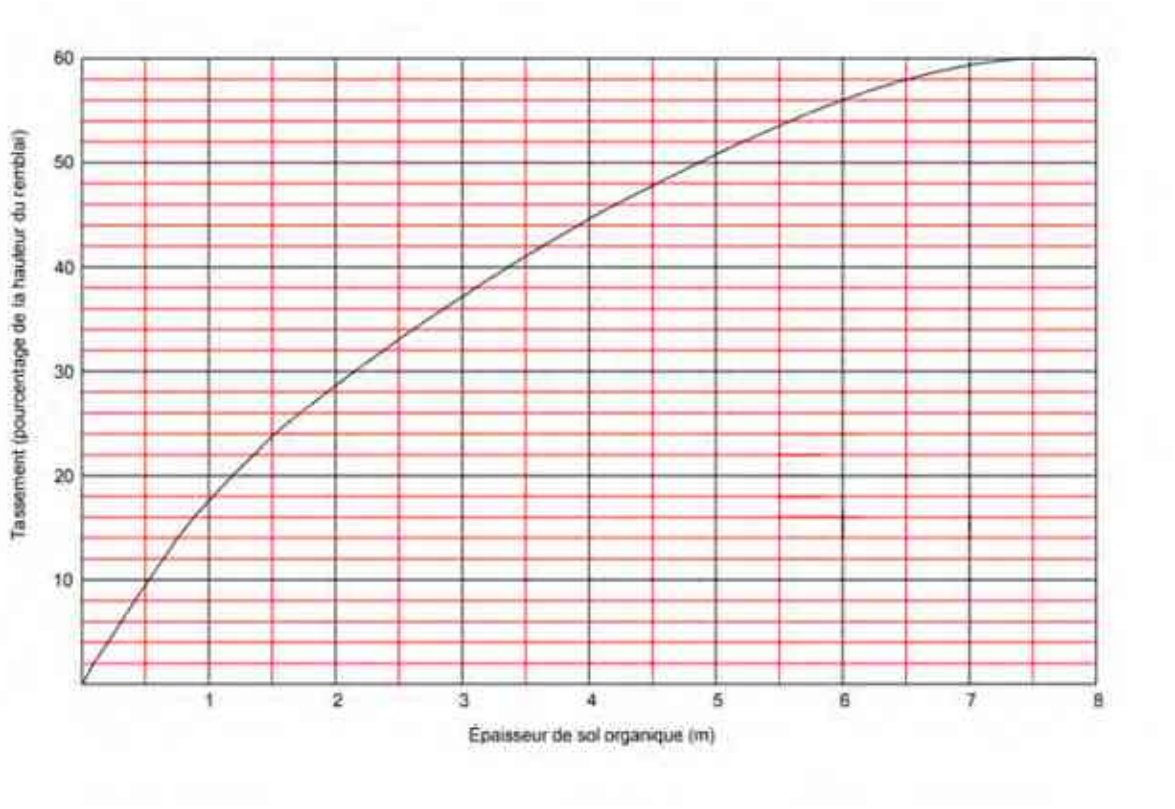

Figure 5 Settlement curve as a function of organic soil thickness (DLC, 2012)

4.3.6 Culverts within Peat Areas

In some cases, temporary drainage of peat areas using culverts may be required to facilitate the construction process. In other cases, the installations of permanents culverts may be required for drainage purposes, or alternatively to maintain a hydraulic connection between portions of the peat areas

to be separated by the rail alignment; the requirements for such culverts would be determined by environmental scientists.

During the construction period, temporary culverts should be installed over and after the initial layer is laid during the peat treatment.

In some cases, permanent culverts may be required to be placed on organic soils that have a considerable thickness. If placing the permanent culvert requires excavation of the organic soils (seating on the mineral soil), grading transitions of 5H:1V, geogrid and 600 mm surcharge should be applied.

4.4 Stability Analysis of Embankments

In addition to stability analyses on high embankments and areas of deep cut, stability analyses will be required in areas of peatlands and/or compressible fine soils.

Organic soils tend to be very compressible and have a low bearing capacity. It will therefore be necessary to ensure that the organic deposit can support the embankment to be placed for the peatland crossover. The short-term stability analysis should consider the undrained shear strength measurements of the organic soils in terms of their vertical and horizontal variability. Anticipated settlement during construction should also be considered in these analyses. A minimum factor of safety of 1.3 is normally judged acceptable for peat stability analyses.

Similarly, it is possible that the mineral deposits underlying the organic soils are too weak to support the embankment without the risk of failure, especially in the presence of soft and compressible fine soils. A geotechnical and stability analysis will be necessary in these areas and will need to account for the behaviour of the organic soils combined with the behaviour of the underlying mineral soils and the minimum safety factor would be 1.5.

In case the minimum safety factors mentioned above cannot be achieved, lowering the embankment profile or height could be considered as a first alternative. Another alternative would be to flatten the embankment slopes and/or add lateral counterweights (berms). The dimensions and geometry of these berms would then be determined by performing new stability calculations. Lastly, if the contribution of the counterweights does not provide sufficient safety factors, light materials such as polystyrene or wood residues could be placed to lighten the embankment (light weight fill).

4.5 Bridges and Culverts

Depressions, watercourses, and roads/roadways along the alignment will be crossed with bridges or culverts.

Each structure will require a detailed geotechnical investigation to supplement the information provided in this preliminary study. Each investigation plan should be based on the proposed structure type and the precise location of the proposed structure. The documents "*Guide de planification et de réalisation des études de reconnaissance de sols"* and its Appendix 1: "*Spécifications pour les forages et sondages d'une étude géotechnique pour le remplacement ou la construction d'ouvrages d'art* " issued by the

Ministère des Transports du Québec should be used as references for the planning of the detailed geotechnical investigations programs. In all cases, the AREMA guidelines regarding soil investigations for the construction of structures should also be considered.

According to the preliminary geotechnical investigation results, soils in the areas of future bridges/culverts may vary greatly from one structure to another. Some structures may rest directly on bedrock or on a dense natural deposit such as the till, where spread footing foundations would be anticipated for bridges, but other structures must be built on highly sensitive and compressible clay soils of significant thickness where piled foundations would be anticipated. As part of the preliminary design considerations, the following can be anticipated.

- Bridge structures in areas underlain clay soils would be supported by piles driven to bedrock, or to refusal within dense till if the dense till is deeper than a few metres.
- Bridges structures in areas underlain by bedrock and dense till would be supported on spread footing foundations.
- Closed box culverts would be anticipated in areas underlain by clay soils, and in some areas, depending on settlement tolerances, the use of light weight fill materials could be required at these culverts.
- Open box culverts would be anticipated in areas underlain by bedrock and dense till.

Special attention will be required in designing the approach embankments to bridges and culverts underlain by clay deposits. For high approach embankments, it should be anticipated that light weight fill (polystyrene blocks) would be required to avoid differential settlements between the structures and the approach embankment fills.

4.6 Railway Structure Design

4.6.1 Ballast and Sub-ballast

The ballast and sub-ballast must be constructed of materials that comply with the Article 2.3.1 of the AREMA. The nature, the manufacturing specifications, as well as the intrinsic properties of the materials used for the railway structure should meet the requirements of this article. In the context of this study, limited research and investigations were carried out on potential borrow pits and quarries located in the vicinity of the alignment to determine the quantities and quality of deposits or bedrock available to be used in the project. Two separate reports were prepared by Stantec to outline these studies (borrow pits and quarries).

The sizing of the ballast and sub-ballast layers must be performed according to AREMA requirements, based on the subgrade conditions encountered in the current summary investigation and the nature and characteristics of the materials to be used (see borrow pits and quarries report).

According to AREMA, a minimum value of 300 mm, after compaction, is recommended for the thickness of ballast and sub-ballast to be placed. These thicknesses must be confirmed in the subsequent

engineering phases, taking into consideration the specific constraints of the project. Furthermore, the requirements of the railway company must be verified. In all cases, to ensure sufficient frost protection of the foundation materials, the total thickness of ballast and sub-ballast should not be less than 600 mm.

4.6.2 Drainage

Adequate drainage is typically provided by ditching, where required, and ensuring that the top of subgrade has a cross-fall of at least 2% to prevent water from accumulating within the sub-ballast and entering the subgrade. Depending on the proposed cut sections, the use of a subdrains may be control groundwater at the base of specific backslope areas, and possibly to lower the water table in areas with highly frost susceptible soils; the design of subdrains should be design with input from a geotechnical engineer.

Ditches will be required to collect surface water, store snow and control rock or debris fall from the cut slopes. The capacity of these ditches will be influenced by their width, depth, and the nature/permeability of the ditch soils. It is recommended to refer to Section 1.2.4 of the AREMA for the design of drainage ditches.

4.7 Recommended Level of Inspection and Testing

To ensure compliance with the design and to confirm assumptions made in this report and by the designers, construction observation, inspection and testing by a geotechnical engineer, as described below, are recommended.

All exposed soils should be inspected by a geotechnical engineer prior to the placement of granular materials. Such inspections are necessary to confirm the expected consistency and nature of the subgrade soils, to ensure that all soft spots have been identified and remediated and that the drainage of surface water has been ensured by the contractor. Subgrade inspections should be carried out to verify nature of the soil subgrade and the granular structure.

All sources of granular materials imported on site should be sampled, tested, and reviewed by a geotechnical engineer.

The placement of granular materials should be observed and tested by geotechnical personnel using nuclear density gauge to ensure all compaction requirements and optimal moisture content are achieved during construction.

APPENDICES

Appendix A Statement of General Conditions

STATEMENT OF GENERAL CONDITIONS

USE OF THIS REPORT: This report has been prepared for the sole benefit of the Client or its agent and may not be used by any third party without the express written consent of Stantec Experts-conseils and the Client. Any use which a third party makes of this report is the responsibility of such third party.

BASIS OF THE REPORT: The information, opinions, and/or recommendations made in this report are in accordance with Stantec Experts-conseils present understanding of the site specific project as described by the Client. The applicability of these is restricted to the site conditions encountered at the time of the investigation or study. If the proposed site specific project differs or is modified from what is described in this report or if the site conditions are altered, this report is no longer valid unless Stantec Experts-conseils is requested by the Client to review and revise the report to reflect the differing or modified project specifics and/or the altered site conditions.

STANDARD OF CARE: Preparation of this report, and all associated work, was carried out in accordance with the normally accepted standard of care in the state or province of execution for the specific professional service provided to the Client. No other warranty is made.

INTERPRETATION OF SITE CONDITIONS: Soil, rock, or other material descriptions, and statements regarding their condition, made in this report are based on site conditions encountered by Stantec Experts-conseils at the time of the work and at the specific testing and/or sampling locations. Classifications and statements of condition have been made in accordance with normally accepted practices which are judgmental in nature; no specific description should be considered exact, but rather reflective of the anticipated material behavior. Extrapolation of in situ conditions can only be made to some limited extent beyond the sampling or test points. The extent depends on variability of the soil, rock and groundwater conditions as influenced by geological processes, construction activity, and site use.

VARYING OR UNEXPECTED CONDITIONS: Should any site or subsurface conditions be encountered that are different from those described in this report or encountered at the test locations, Stantec Experts-conseils must be notified immediately to assess if the varying or unexpected conditions are substantial and if reassessments of the report conclusions or recommendations are required. Stantec Experts-conseils will not be responsible to any party for damages incurred as a result of failing to notify Stantec Experts-conseils that differing site or sub-surface conditions are present upon becoming aware of such conditions.

PLANNING, DESIGN, OR CONSTRUCTION: Development or design plans and specifications should be reviewed by Stantec Experts-conseils, sufficiently ahead of initiating the next project stage (property acquisition, tender, construction, etc), to confirm that this report completely addresses the elaborated project specifics and that the contents of this report have been properly interpreted. Specialty quality assurance services (field observations and testing) during construction are a necessary part of the evaluation of sub-subsurface conditions and site preparation works. Site work relating to the recommendations included in this report should only be carried out in the presence of a qualified geotechnical engineer; Stantec Experts-conseils cannot be responsible for site work carried out without being present.

Appendix C Borehole Reports

BOREHOLE REPORT

Project:	La Grande Alliance - Feasibility Study - Phase I	Coordinate :	Geo. System : UTM Zone: 18	Borehole :	BH22-01
		X :	312 812	Page :	1 of 1
Project No.:	158100425.500.710.5	Y :	5 516 753	Start date :	2000-09-20
Client:	Cree Development Corporation	Type of borehole :	Hollow Stem Auger + Diamond Core	Inspector :	A. Bogaert, tech.
Site:	Preliminary Geotechnical Investigation	Equipment :	CME 55	Depth :	2,52 m
	Potential BDH Railway	Sampling type :	B, N		
		Corer :	NQ	Figure :	01

SAMPLE TYPE

SS	Split spoon
CS	Continuous sampling
DC	Diamond rock core
AS	Auger
TW	Thin wall sampler
ST	Shelby tube
MA	Manual sample

QUALITATIVE TERMINOLOGY

Clay	< 0.002 mm
Silt	0.002 - 0.08 mm
Sand	0.08 - 5 mm
Gravel	5 - 80 mm
Cobbles	80 - 200 mm
Boulders	> 200 mm

QUANTITATIVE TERMINOLOGY

Traces	< 10 %
Some	10 - 20 %
Adjective (...y)	20 - 35 %
and (ex: and gravel)	> 35 %
Main word	Dominant fraction

SYMBOLS

N	Standard penetration value (ASTM D 1586)
Nc	Dynamic cone penetration value (BNQ 2501-145)
RQD	Rock Quality Designation (%)

GROUNDWATER

	Date	Depth
Reading 1		m
Reading 2		m

Remarks :

SAMPLE STATE

- Remoulded
- Intact (thin wall sampler)
- Lost
- Core (diamond rock core)

MECHANIC CHARACTERISTICS OF SOILS

COMPACTION	INDEX "N"	CONSISTENCY	Cu OR Su (kPa)
Very loose	0 - 4	Very soft	< 12
Loose	4 - 10	Soft	12 - 25
Compact	10 - 30	Firm	25 - 50
Dense	30 - 50	Stiff	50 - 100
Very dense	> 50	Very stiff	100 - 200
		Hard	> 200

ROCK QUALITY DESIGNATION

QUALIFICATIVE	RQD
Very poor	< 25 %
Poor	25 - 50 %
Fair	50 - 75 %
Good	75 - 90 %
Excellent	90 - 100 %

JOINTS SPACING

Very tight	< 20 mm
Tight	20 - 60 mm
Close	60 - 200 mm
Moderately spaced	200 - 600 mm
Spaced	600 - 2000 mm
Very spaced	2000 - 6000 mm
Wide	> 6000 mm

STRATIGRAPHY / SAMPLES / TESTS

DEPTH (m)	DEPTH (ft)	DEPTH (m)	DESCRIPTION OF SOILS AND ROCK	SYMBOL	STATE	TYPE N°	SUB - SAMPLE	CALIBER	RECOVERY (%)	N - RQD	Standard penetration test BLOWS/150mm	WATER LEVEL / WATER INFLOW	TESTS	REMARKS
		0,00												
		0,05	Brown-black moist TOPSOIL. Native till deposit : Grey moist SILT and SAND with traces of gravel and clay, very dense.			SS-01	A / B	N	50		2-7-16-15			
						SS-02		B	80	R	17-28-50 /8 cm		GA, H	
1	5	0,99	Bedrock : Grey SANDSTONE, of fair quality.			DC-03		NQ	100	62			f'c = 110,1 MPa U.W. = 27.2 kN/m³	
2		2,52	END OF BOREHOLE

One-Dimensional Consolidation Test using Incremental Loading

ASTM D2435/D2435M - 11(2020)

Specimen Details

Project Name	La Grande Alliance - Feasibility Study - Phase I - Preliminary Geotechnical Investigation
Project Location	Potential BDH Railway
Borehole Sample	BH22-12
No. Depth	ST-21
Sample Date Test	4.27-4.88 m.
Number	September 21, 2022
Technician Name	One
	Daniel Boateng

Soil Description & Classification

Silty clay, grey, friable, very wet	
Specific Gravity of Solids	2.750
Average water content of trimmings %	81.24
Additional Notes (information source, occurence and size of large isolated particles etc.)	
Specific Gravity of Solids was Assumed	

Initial Specimen Conditions

Height	mm	20.00
Diameter	mm	50.00
Area	mm^2	1963
Volume	mm^3	39270
Mass	g	58.98
Dry Mass	g	31.56
Density	Mg/m^3	1.502
Dry Density	Mg/m^3	0.804
Water Content	%	86.88
Degree of Saturation	%	98.7
Height of Solids	mm	5.84
Initial Void Ratio		2.422

Final Specimen Conditions

Water Content	%	49.21
Final Void Ratio		1.204
Final Height	mm	12.88

One-Dimensional Consolidation Test using Incremental Loading

ASTM D2435/D2435M - 11(2020)

Specimen Details

Project Name	La Grande Alliance - Feasibility Study - Phase I - Preliminary Geotechnical Investigation
Project Location	Potential BDH Railway
Borehole Sample	BH22-15
No. Depth	ST-05
Sample Date	2.44-3.05 m
Test Number	October 17, 2022
Technician Name	Seven
	Daniel Boateng

Soil Description & Classification

Silty clay, grey, friable, very wet	
Specific Gravity of Solids	2.750
Average water content of trimmings %	95.38
Additional Notes (information source, occurence and size of large isolated particles etc.)	
1. Specific gravity of solids was assumed, 2. Sample did not rebound due to significant strain	

Initial Specimen Conditions

Height	mm	20.00
Diameter	mm	50.00
Area	mm^2	1963
Volume	mm^3	39270
Mass	g	56.55
Dry Mass	g	27.51
Density	Mg/m^3	1.440
Dry Density	Mg/m^3	0.701
Water Content	%	105.56
Degree of Saturation	%	99.2
Height of Solids	mm	5.09
Initial Void Ratio		2.926

Final Specimen Conditions

Water Content	%	47.40
Final Void Ratio		0.967
Final Height	mm	10.02

One-Dimensional Consolidation Test using Incremental Loading

ASTM D2435/D2435M - 11(2020)

Specimen Details

Project Name	La Grande Alliance - Feasibility Study - Phase I - Preliminary Geotechnical Investigation
Project Location	Potential BDH Railway
Borehole Sample	BH22-18
No. Depth	ST-20
Sample Date Test	7.32-7.93 m.
Number	September 23, 2022
Technician Name	Three
	Daniel Boateng

Soil Description & Classification

Silty clay, grey, friable, wet	
Specific Gravity of Solids	2.750
Average water content of trimmings %	69.10
Additional Notes (information source, occurence and size of large isolated particles etc.)	
Specific Gravity of Solids was Assumed	

Initial Specimen Conditions

Height	mm	20.00
Diameter	mm	50.00
Area	mm^2	1963
Volume	mm^3	39270
Mass	g	62.11
Dry Mass	g	37.13
Density	Mg/m^3	1.582
Dry Density	Mg/m^3	0.946
Water Content	%	67.28
Degree of Saturation	%	96.9
Height of Solids	mm	6.88
Initial Void Ratio		1.908

Final Specimen Conditions

Water Content	%	45.14
Final Void Ratio		1.117
Final Height	mm	14.56

Number	November 3, 2022
Technician Name	10
	Daniel Boateng

Test Procedure

Date Started		December 2, 2022
Date Finished		December 3, 2022
Machine Number		Frame F
Cell Number		F
Ring Number		F
Trimming Procedure		Cutting ring/Trimming turntable
Moisture Condition		Inundated
Axial Stress at Inundation	kPa	5
Water Used		De-aired Tap Water
Test Method		B
Interpretation Procedure for c_v		2

All Departures from Outlined ASTM D2435/D2435M-11 (2020) Procedure

One-Dimensional Consolidation Test using Incremental Loading

ASTM D2435/D2435M - 11(2020)

Specimen Details

Project Name	La Grande Alliance - Feasibility Study - Phase I - Preliminary Geotechnical Investigation
Project Location	Potential BDH Railway
Borehole Sample	BH22-25
No. Depth	ST-22
Sample Date Test	6.10-6.71 m.
Number	September 23, 2022
Technician Name	Five
	Daniel Boateng

Soil Description & Classification

Silty clay, grey, friable, very wet	
Specific Gravity of Solids	2.750
Average water content of trimmings %	80.90
Additional Notes (information source, occurence and size of large isolated particles etc.)	
Specific Gravity of Solids was Assumed	

Initial Specimen Conditions

Height	mm	20.00
Diameter	mm	50.00
Area	mm^2	1963
Volume	mm^3	39270
Mass	g	59.46
Dry Mass	g	32.66
Density	Mg/m^3	1.514
Dry Density	Mg/m^3	0.832
Water Content	%	82.06
Degree of Saturation	%	97.8
Height of Solids	mm	6.05
Initial Void Ratio		2.307

Final Specimen Conditions

Water Content	%	44.70
Final Void Ratio		1.160
Final Height	mm	13.06

One-Dimensional Consolidation Test using Incremental Loading

ASTM D2435/D2435M - 11(2020)

Specimen Details

Project Name	LGA Geotechnical Study-Railway Investigations
Project Location	Quebec, Canada-(Billy Diamond Site)
Borehole	BH22-28
Sample No.	ST-06
Depth	3.05-3.66 m
Sample Date	November 4, 2022
Test Number	11
Technician Name	Daniel Boateng

Soil Description & Classification

Silty clay, brown/grey, friable/desiccated, very moist

Specific Gravity of Solids		2.750
Average water content of trimmings	%	46.65

Additional Notes (information source, occurence and size of large isolated particles etc.)

Specific gravity of solids was assumed

Initial Specimen Conditions

Height	mm	20.00
Diameter	mm	50.00
Area	mm^2	1963
Volume	mm^3	39270
Mass	g	67.22
Dry Mass	g	45.64
Density	Mg/m^3	1.712
Dry Density	Mg/m^3	1.162
Water Content	%	47.28
Degree of Saturation	%	95.2
Height of Solids	mm	8.45
Initial Void Ratio		1.366

Final Specimen Conditions

Water Content	%	36.79
Final Void Ratio		0.945
Final Height	mm	16.44

One-Dimensional Consolidation Test using Incremental Loading

ASTM D2435/D2435M - 11(2020)

Specimen Details

Project Name	La Grande Alliance - Feasibility Study - Phase I - Preliminary Geotechnical Investigation
Project Location	Potential BDH Railway
Borehole Sample	BH22-30
No. Depth	ST-07
Sample Date Test	3.66-4.27 m
Number	Thursday, October 6, 2022
Technician Name	Eight
	Daniel Boateng

Soil Description & Classification

Silty clay, dark grey, trace gravel, moist	
Specific Gravity of Solids	2.750
Average water content of trimmings %	45.98
Additional Notes (information source, occurence and size of large isolated particles etc.)	
Specific gravity of solids was assumed	

Initial Specimen Conditions

Height	mm	20.00
Diameter	mm	50.00
Area	mm^2	1963
Volume	mm^3	39270
Mass	g	68.84
Dry Mass	g	46.77
Density	Mg/m^3	1.753
Dry Density	Mg/m^3	1.191
Water Content	%	47.19
Degree of Saturation	%	99.1
Height of Solids	mm	8.66
Initial Void Ratio		1.309

Final Specimen Conditions

Water Content	%	31.20
Final Void Ratio		0.810
Final Height	mm	15.68

Stantec Consulting Ltd.

One-Dimensional Consolidation Test using Incremental Loading
ASTM D2435/D2435M - 11(2020)

Specimen Details

Job Ref.	La Grande Alliance - Feasibility Study - Phase I - Preliminary Geotechnical Investigation
Job Location	Potential BDH Railway
Borehole Sample	BH22-36
No. Depth	ST-09
Sample Date Test	6.71-7.32 m.
Number	October 11, 2022
Technician Name	Six
	Daniel Boateng

Calculations

		Calculated using Interpretation Procedure 2				Interpretation Procedure 1		Interpretation Procedure 2	
Load Increment	Axial Stress $\sigma_{a,\ average}$ kPa	Corrected Deformation ΔH_{50} mm	Specimen Height H_{50} mm	Axial Strain $\varepsilon_{a,50}$ %	Void Ratio e_{50}	Time t_{50} sec	Coeff. Consol. c_v mm^2/s	Time t_{90} sec	Coeff. Consol. c_v mm^2/s

Investigation Summary

City/region : Baie James (Billy Diamond road)	Project : La Grande Alliance - Feasability Study - Phase 1
KP :	Project # : 158100425.500.750.4
Client: Cree Development Corporation	Geotechnical Project Manager : Timothée Coulaux, ing.
Date : 02/08/2022 to 12/08/2022	Technician(s) : Raphaelle Croteau & Élie Ferland
Survey type: Manual auger surveying (TA), Manual scisometer test (SC)	

Survey	Localisation (m)					Depth (m)		Description	Scisometer (kPa) (Depth m)	Approximate water level BGS (cm)	Von Post Classification	Comments
	KP	Offset (m)		Coordinates (MTM9)								
		L	R	X	Y	From	To					
Site #2: Peatland on brownish/greyish silty clay, flat topography, Subsurface water ≈5cm below ground surface (BGS), machinery tracks on site, light tree coverage, light herbaceous coverage												
TA02-01	4.4	0	0	221101	5513820	0	0.45	Peat	30 (0.25)	5	H7	
						0.45	0.55	clay	118 (0.55)			
TA02-02	4.4	0	0	221133	5513830	0	0.35	Peat		5	H7	
						0.35	+	clay, some silt				
Site #3: Forested peatland on brown silty clay with some sand, flat topography, Subsurface water flush with ground surface, logging activities (clear cut), no tree coverage, moderate herbaceous coverage												
TA03-01	5.1	0	0	221582	5514200	0	0.5	Peat	16 (0.25)		H5	
						0.5	0.75	Clay	124 (0.75)			
TA03-02	5.1	0	0	221582	5514200	0	0.4	Peat			H5	
						0.4	+	Clay				
Site #4: Presence of peatmoss but not totally a peatland,Strong slope descending toward SW, till hill East of site, blocks on the ground east of site, moderate tree coverage, no herbaceous coverage												
TA04-01	9.1	0	0	225139	5515860	0	0.2	Peat			H2	
						0.2	+	Till				
Site #5: forested peatland on brown silty clay, light slope descending toward NE, dense tree coverage, light herbaceous coverage												
TA05-01	11.2	0	0	227289	5515650	0	0.25	Peat			H1-2	
						0.25	0.35	Silty clay	96 (0.3)			
TA05-02	11.2	0	0	227318	5515660	0	0.15	Peat			H2	
						0.15	+	Sandy silt, some clay				
Site #6: forested peatland on brownish/beige clayey silt with traces of sand, flat topography, dense tree coverage, moderate herbaceous coverage												
TA06-01	12.3	0	0	228172	5516290	0	0.45	Peat	21 (0.3)		H1	
						0.45	0.6	Clayey silt	126 (0.6)			
TA06-02	12.3	0	0	228189	5516300	0	0.5	Peat			H2	
						0.5	+	Clayey silt				
Site #7: forested peatland on grey clay with traces of silt, flat topography, small water stream near TA07-01, moderate tree coverage, moderate herbaceous coverage												
TA07-01	13.7	0	0	228972	5517480	0	0.43	Peat	12 (0.3)	10	H4	
						0.43	0.8	Clay	86 (0.8)	10

Surficial Material

Surficial Material Classification

R	> 80 % of bedrock
T	Till
SG	Sand and Gravel
S	Sand
SM	Silty sand or sandy silt
CM	Clayey silt or silty clay
Pt	Peat
B	Boulders*
BE	Existing borrow Source
N	Water body
Ant	Anthropogenic

Examples of Layer Overlapping and Thickness

Sm/T	Thin layer of sand (< 2 m thick) over till
S/T	Layer of sand (2 to 6 m thick) over till
S	Sand (> 6 m thick)

Examples of Combined Symbols

T+B	Till with boulders at the ground surface
R+Tm/R	Bedrock with a veneer of till (< 2 m thick)
T-SG	Undifferentiated till or sand and gravel

** No Thickness was Interpreted for Boulder Accumulations*

Generalized Surficial Material Classification

- Sand and gravel (< 2 m thick)
- Sand (> 2 m thick)
- Silty sand or sandy silt (< 2 m thick)
- Clayey silt or silty clay (> 2 m thick)
- Peat (< 2 m thick)
- Anthropogenic

Surficial Material

Surficial Material Classification

R	> 80 % of bedrock
T	Till
SG	Sand and Gravel
S	Sand
SM	Silty sand or sandy silt
CM	Clayey silt or silty clay
Pt	Peat
B	Boulders*
BE	Existing borrow Source
N	Water body
Ant	Anthropogenic

Examples of Layer Overlapping and Thickness

Sm/T	Thin layer of sand (< 2 m thick) over till
S/T	Layer of sand (2 to 6 m thick) over till
S	Sand (> 6 m thick)

Examples of Combined Symbols

T+B	Till with boulders at the ground surface
R+Tm/R	Bedrock with a veneer of till (< 2 m thick)
T-SG	Undifferentiated till or sand and gravel

** No Thickness was Interpreted for Boulder Accumulations*

Generalized Surficial Material Classification

- Till (> 2 m thick)
- Sand and gravel (< 2 m thick)
- Silty sand or sandy silt (< 2 m thick)
- Silty sand or sandy silt (> 2 m thick)
- Clayey silt or silty clay (> 2 m thick)
- Peat (< 2 m thick)

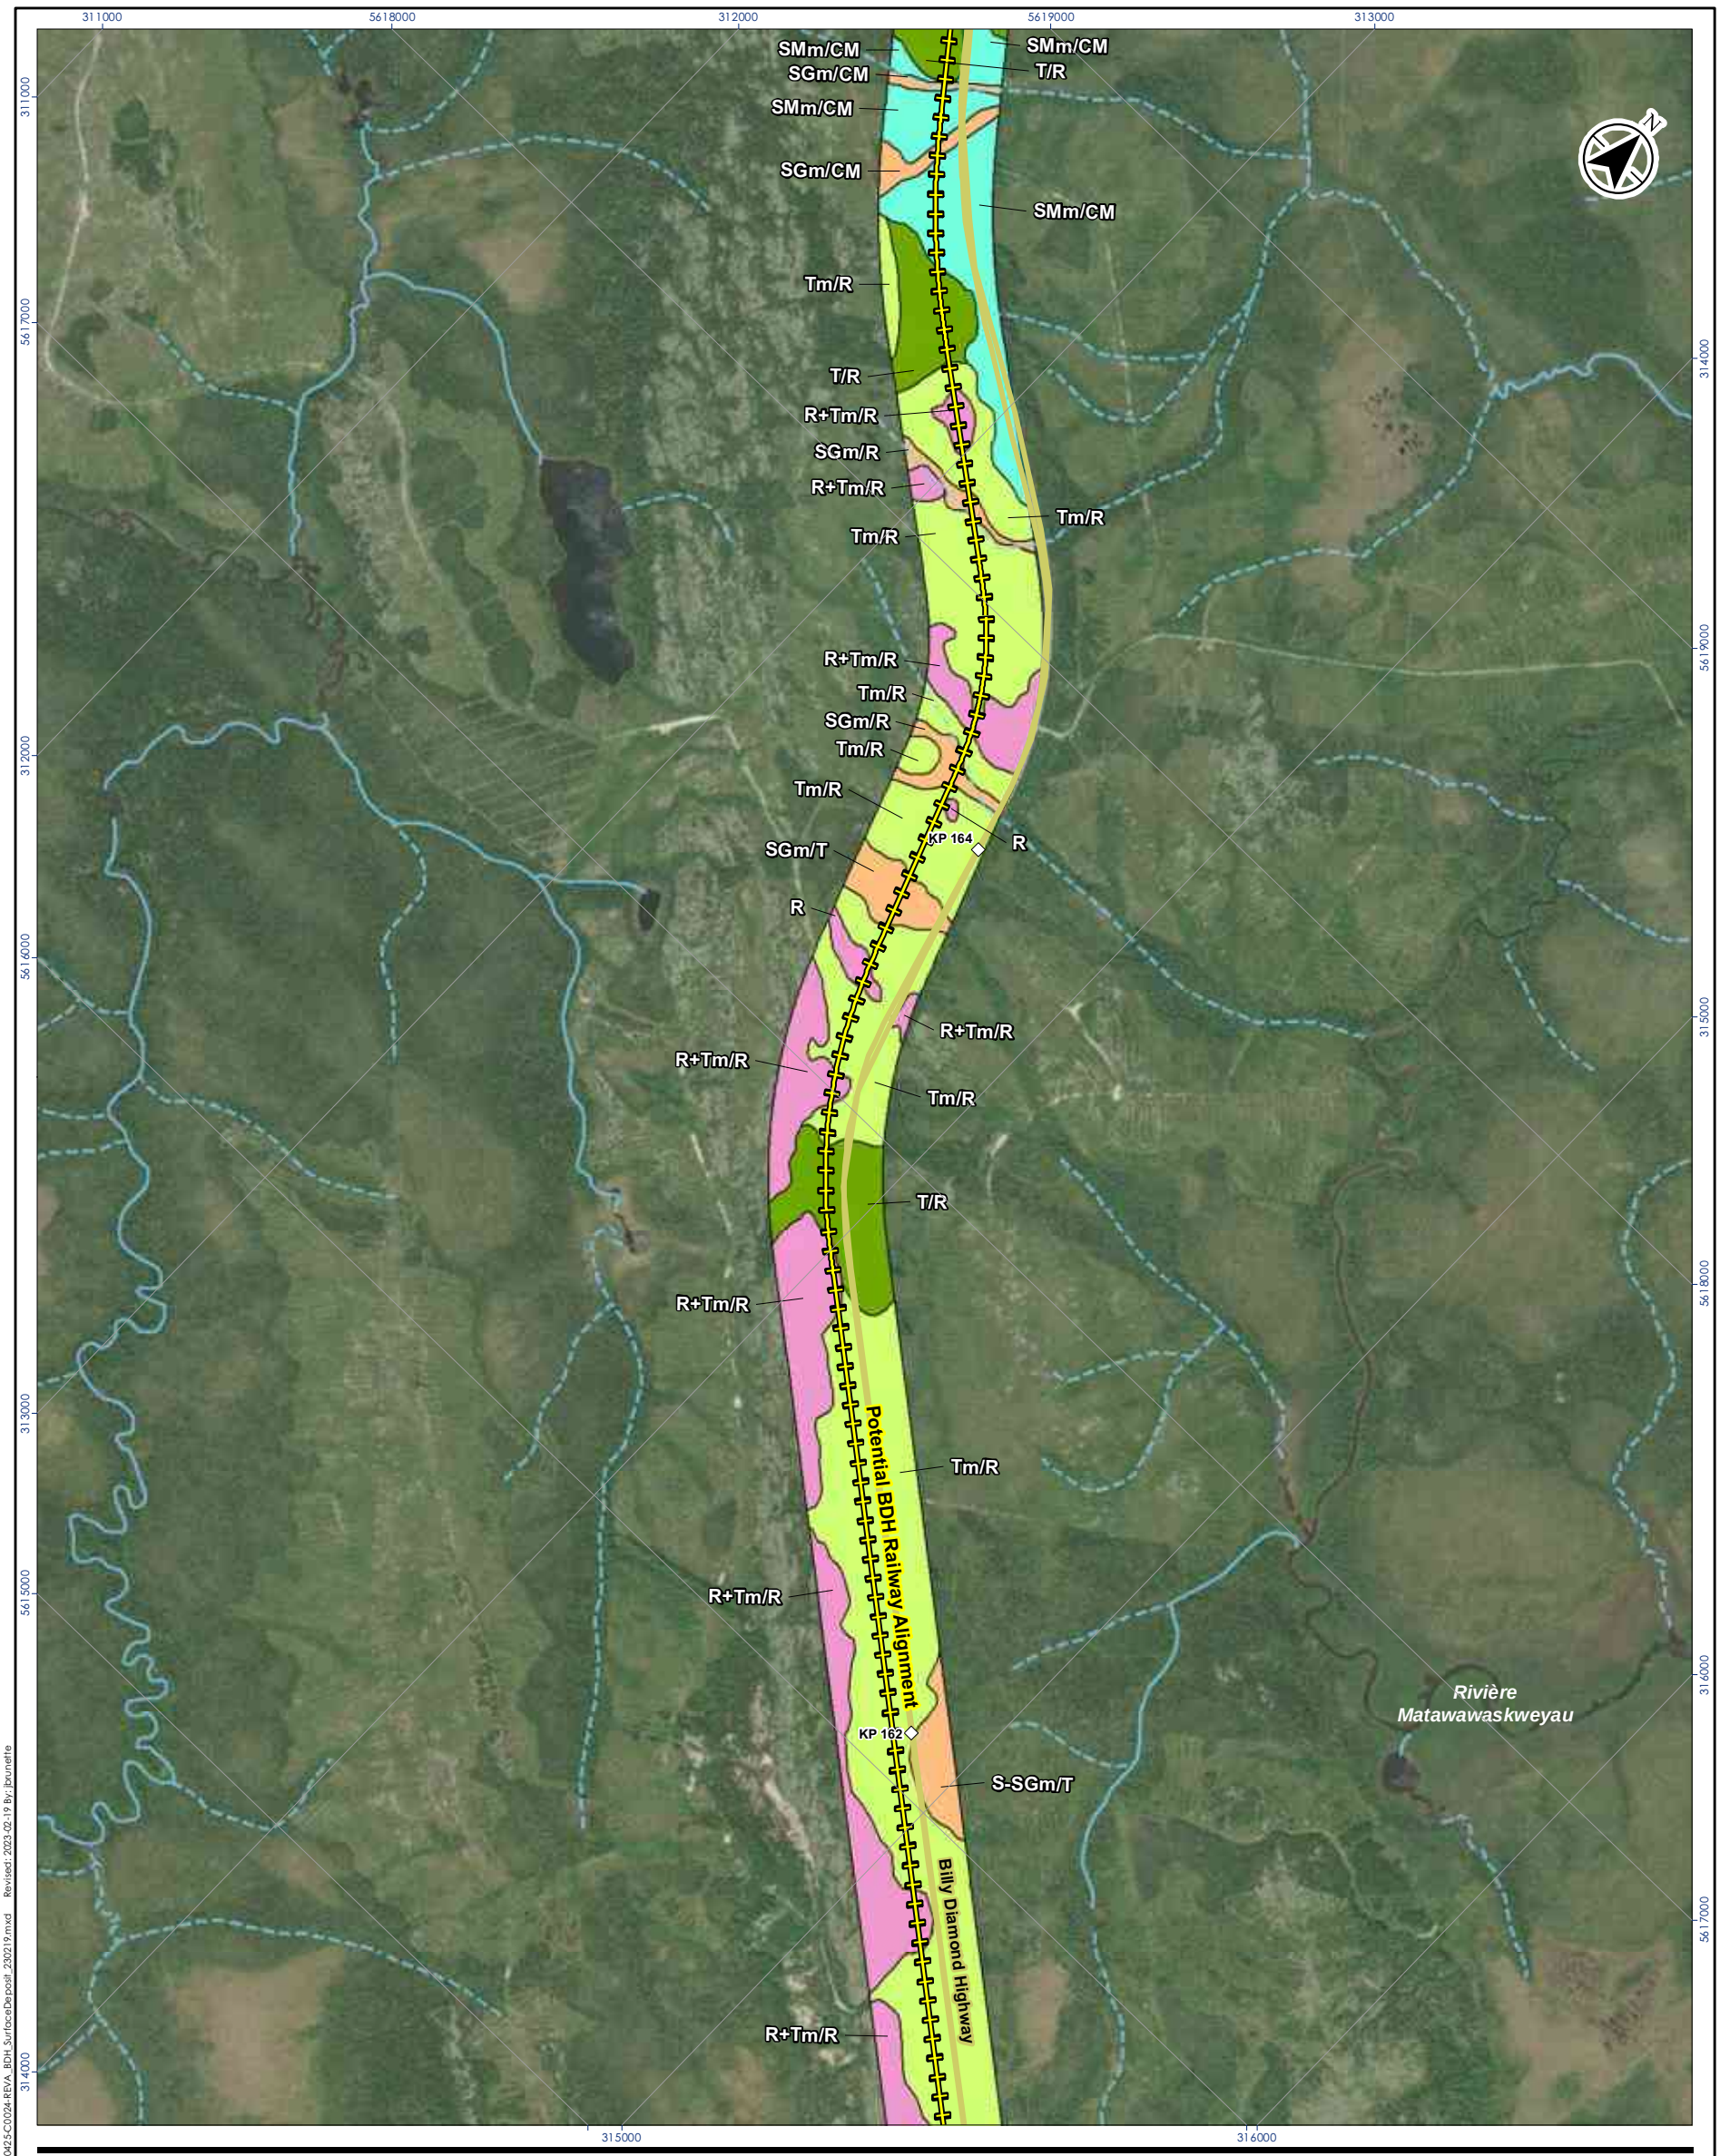
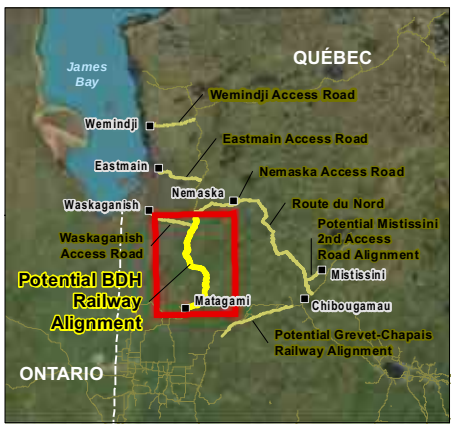
\\ca0119-pfs01\projets_partages\158100425\GO\6-Geomatique\2-Carto\1_MXD\P158100425_Geomorphology\158100425-C0024-REVA_BDH_SurfaceDeposit_230219.mxd Revised: 2023-02-19 By: jbrunette





Notes

1. Coordinate System: NAD 1983 CSRS MTM 9
2. Surficial Material: Stantec, 2023
3. Road Network: Adresses Québec, 2021 and MTQ, 2021
4. Hydrography: GRHQ, 2017
5. Orthoimagery: ESRI-World Imagery, 2012 to 2021

0 0,15 0,3 Km

1:15 000 (At Original document size of 11x17)

Projected Component

Potential BDH Railway Alignment

Hydrography

Permanent Watercourse

Intermittent Watercourse

Road

Kilometric Point (MTQ, 2021)

Road

Surficial Material

Surficial Material Classification

R	> 80 % of bedrock
T	Till
SG	Sand and Gravel
S	Sand
SM	Silty sand or sandy silt
CM	Clayey silt or silty clay
Pt	Peat
B	Boulders*
BE	Existing borrow Source
N	Water body
Ant	Anthropogenic

Examples of Layer Overlapping and Thickness

Sm/T	Thin layer of sand (< 2 m thick) over till
S/T	Layer of sand (2 to 6 m thick) over till
S	Sand (> 6 m thick)

Examples of Combined Symbols

T+B	Till with boulders at the ground surface
R+Tm/R	Bedrock with a veneer of till (< 2 m thick)
T-SG	Undifferentiated till or sand and gravel

** No Thickness was Interpreted for Boulder Accumulations*

Generalized Surficial Material Classification

- Bedrock
- Till (< 2 m thick)
- Till (> 2 m thick)
- Sand and gravel (< 2 m thick)
- Silty sand or sandy silt (< 2 m thick)
